Bagging and Boosting in R

Kamal Mishra | Mohammad J Asad
23-Feb-2020

Agenda

- Background
- Examples around motivation
- Need for the usage
- Difference between Bagging and Boosting
- Algorithms
- Deep dive on few techniques
- Different practice usage in R
- References
- Q&A

Background

- Single decision tree does not perform well. Very simple, of course easy to interpret, however underperforms. Does not work for complex business scenarios
- Variance ?? – reduction !!
- Aggregating multiple decision trees for same training dataset performs better in test data - >> bagging
- Aggregate multiple decision trees >> reduces variance... and hence improves accuracy and prediction performance

Examples around motivation

- Let's look at sample data for understanding and illustrative comparison
- Car Seats dataset: A simulated data set containing sales of child car seats at 400 different stores. – comes default in R

```
> head(Carseats)
```

	Sales	CompPrice	Income	Advertising	Population	Price	ShelveLoc	Age	Education	Urban	US
1	9.50	138	73	11	276	120	Bad	42		17	Yes Yes
2	11.22	111	48	16	260	83	Good	65		10	Yes Yes
3	10.06	113	35	10	269	80	Medium	59		12	Yes Yes
4	7.40	117	100	4	466	97	Medium	55		14	Yes Yes
5	4.15	141	64	3	340	128	Bad	38		13	Yes No
6	10.81	124	113	13	501	72	Bad	78		16	No Yes

```
> str(Carseats)
```

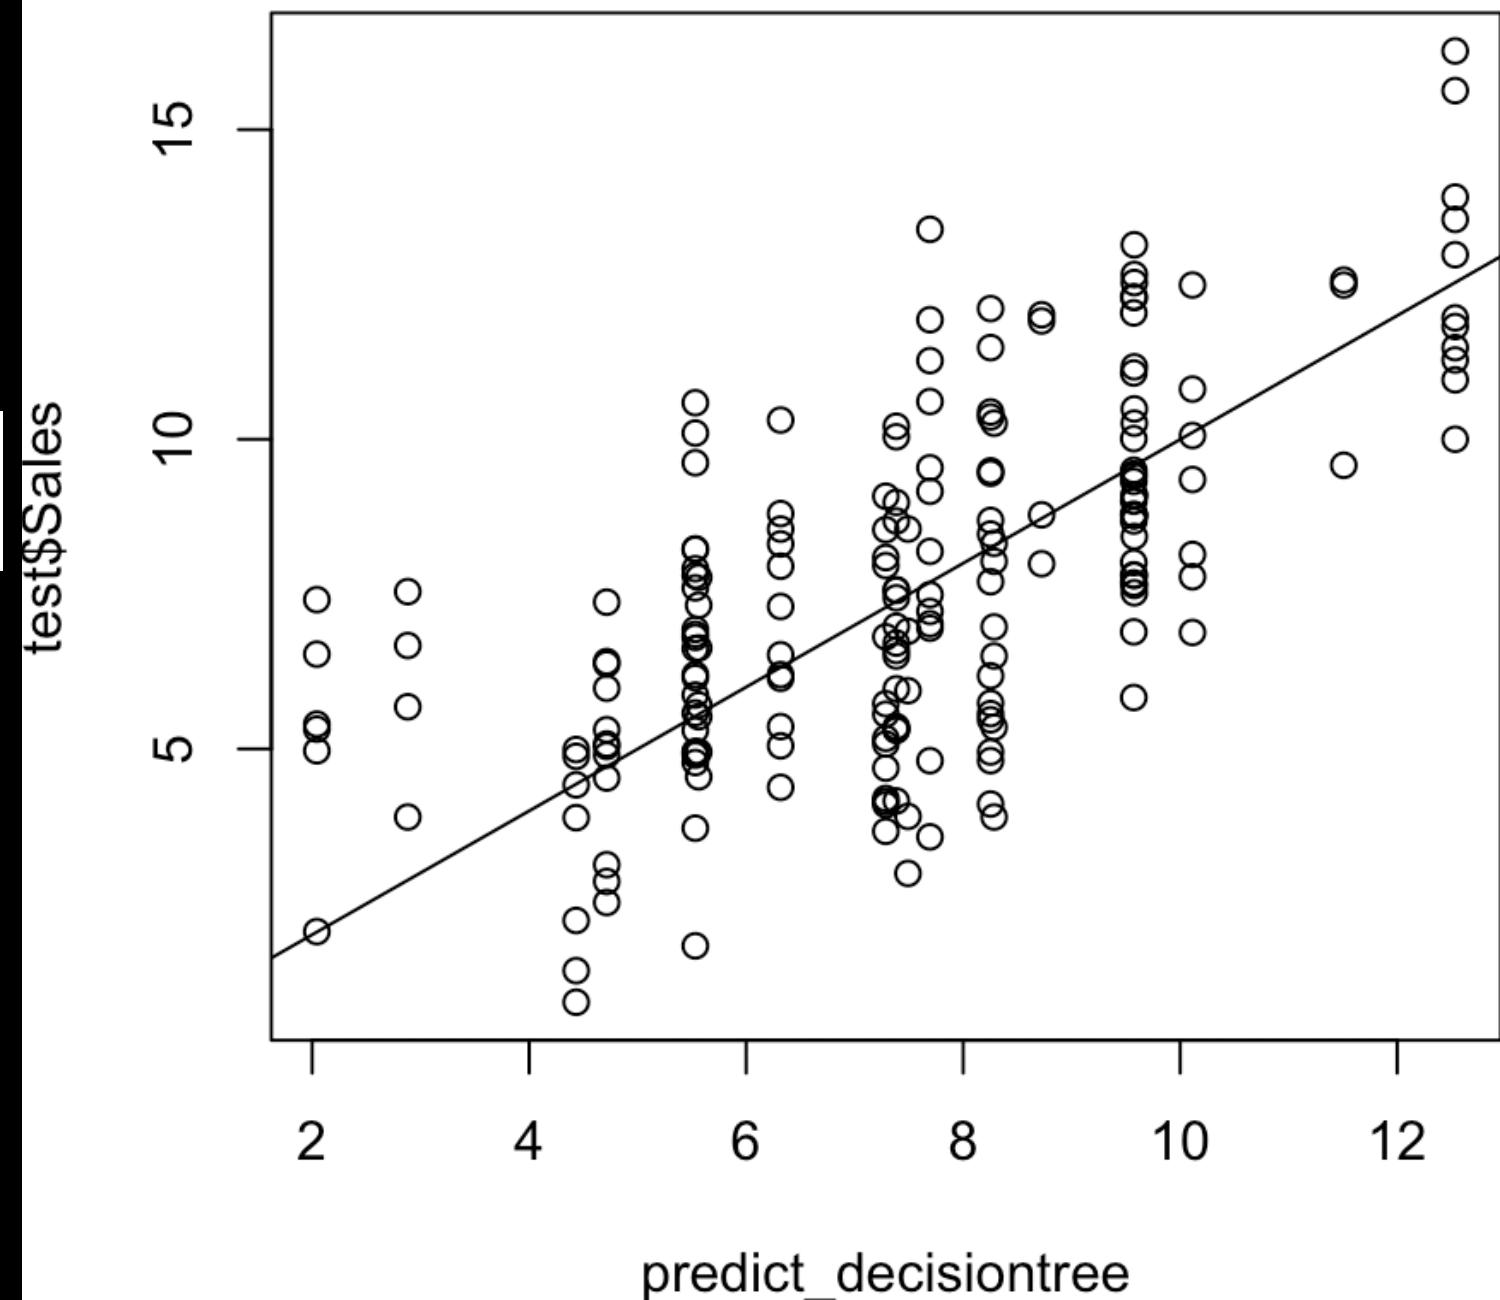

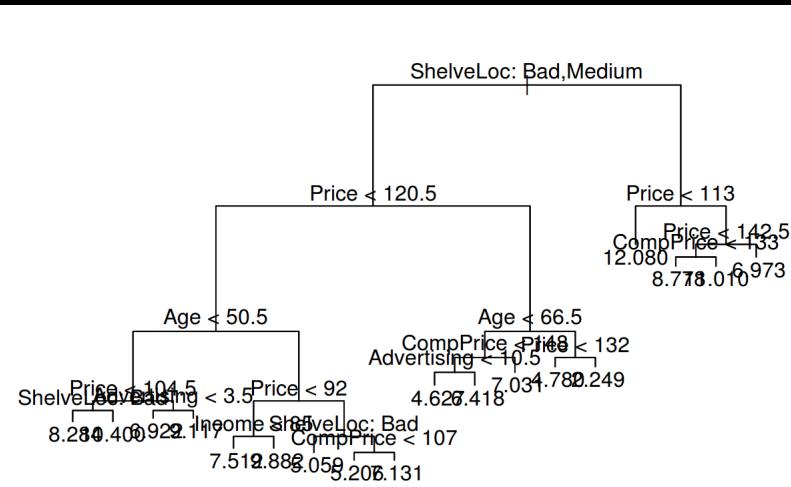

'data.frame': 400 obs. of 11 variables:

\$ Sales : num 9.5 11.22 10.06 7.4 4.15 ...
\$ CompPrice : num 138 111 113 117 141 124 115 136 132 132 ...
\$ Income : num 73 48 35 100 64 113 105 81 110 113 ...
\$ Advertising: num 11 16 10 4 3 13 0 15 0 0 ...
\$ Population : num 276 260 269 466 340 501 45 425 108 131 ...
\$ Price : num 120 83 80 97 128 72 108 120 124 124 ...
\$ ShelveLoc : Factor w/ 3 levels "Bad", "Good", "Medium": 1 2 3 3 1 1 3 2 3 3 ...
\$ Age : num 42 65 59 55 38 78 71 67 76 76 ...
\$ Education : num 17 10 12 14 13 16 15 10 10 17 ...
\$ Urban : Factor w/ 2 levels "No", "Yes": 2 2 2 2 2 1 2 2 1 1 ...
\$ US : Factor w/ 2 levels "No", "Yes": 2 2 2 2 1 2 1 2 1 2 ...

Decision Tree

- MSE = 4.74

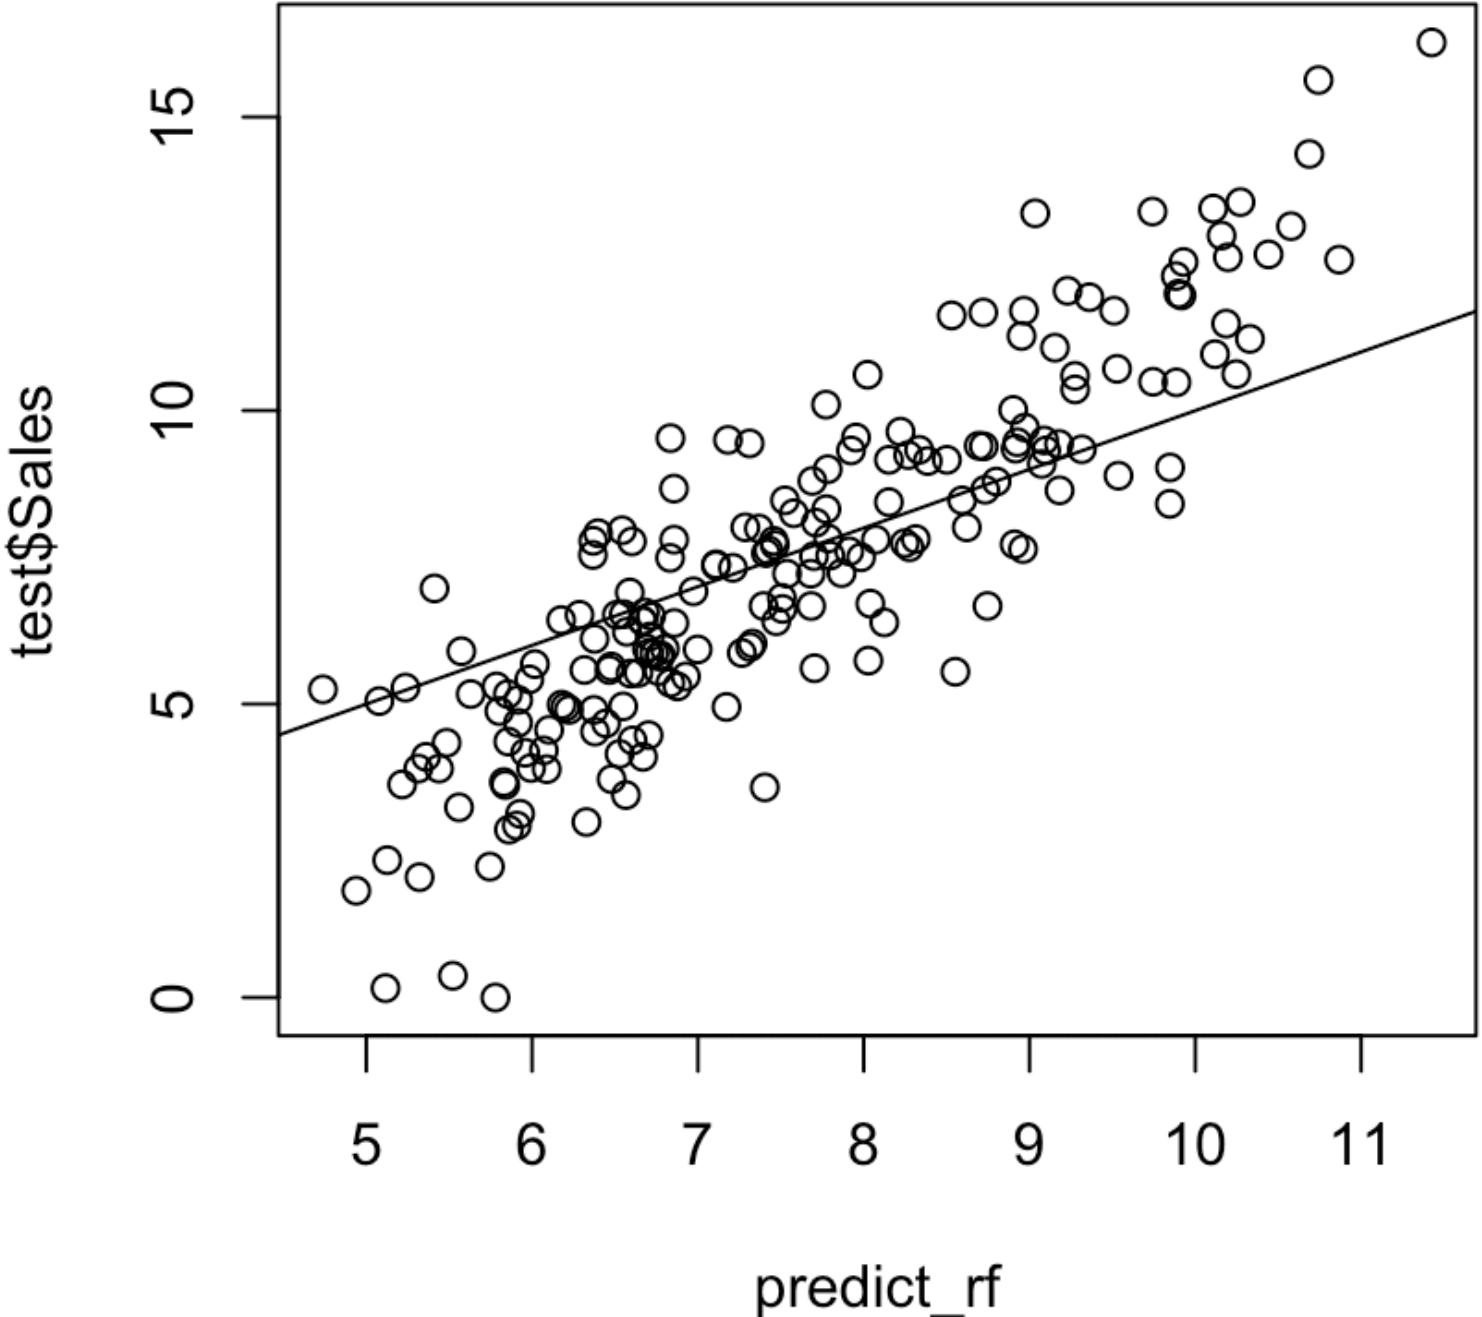

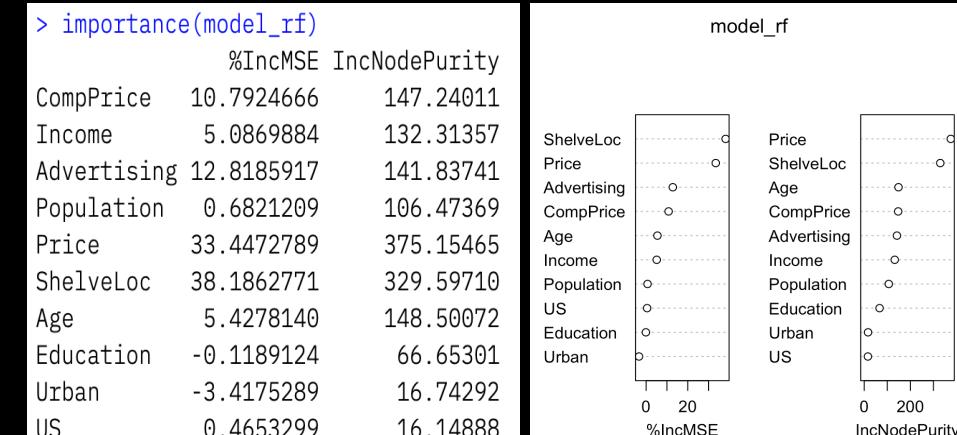

```
> model_decisiontree = tree(Sales ~ ., data = train)
> predict_decisiontree = predict(model_decisiontree, test)
> mean((predict_decisiontree - test$Sales)^2)
[1] 4.7397
```

Random Forest

- MSE = 3.10

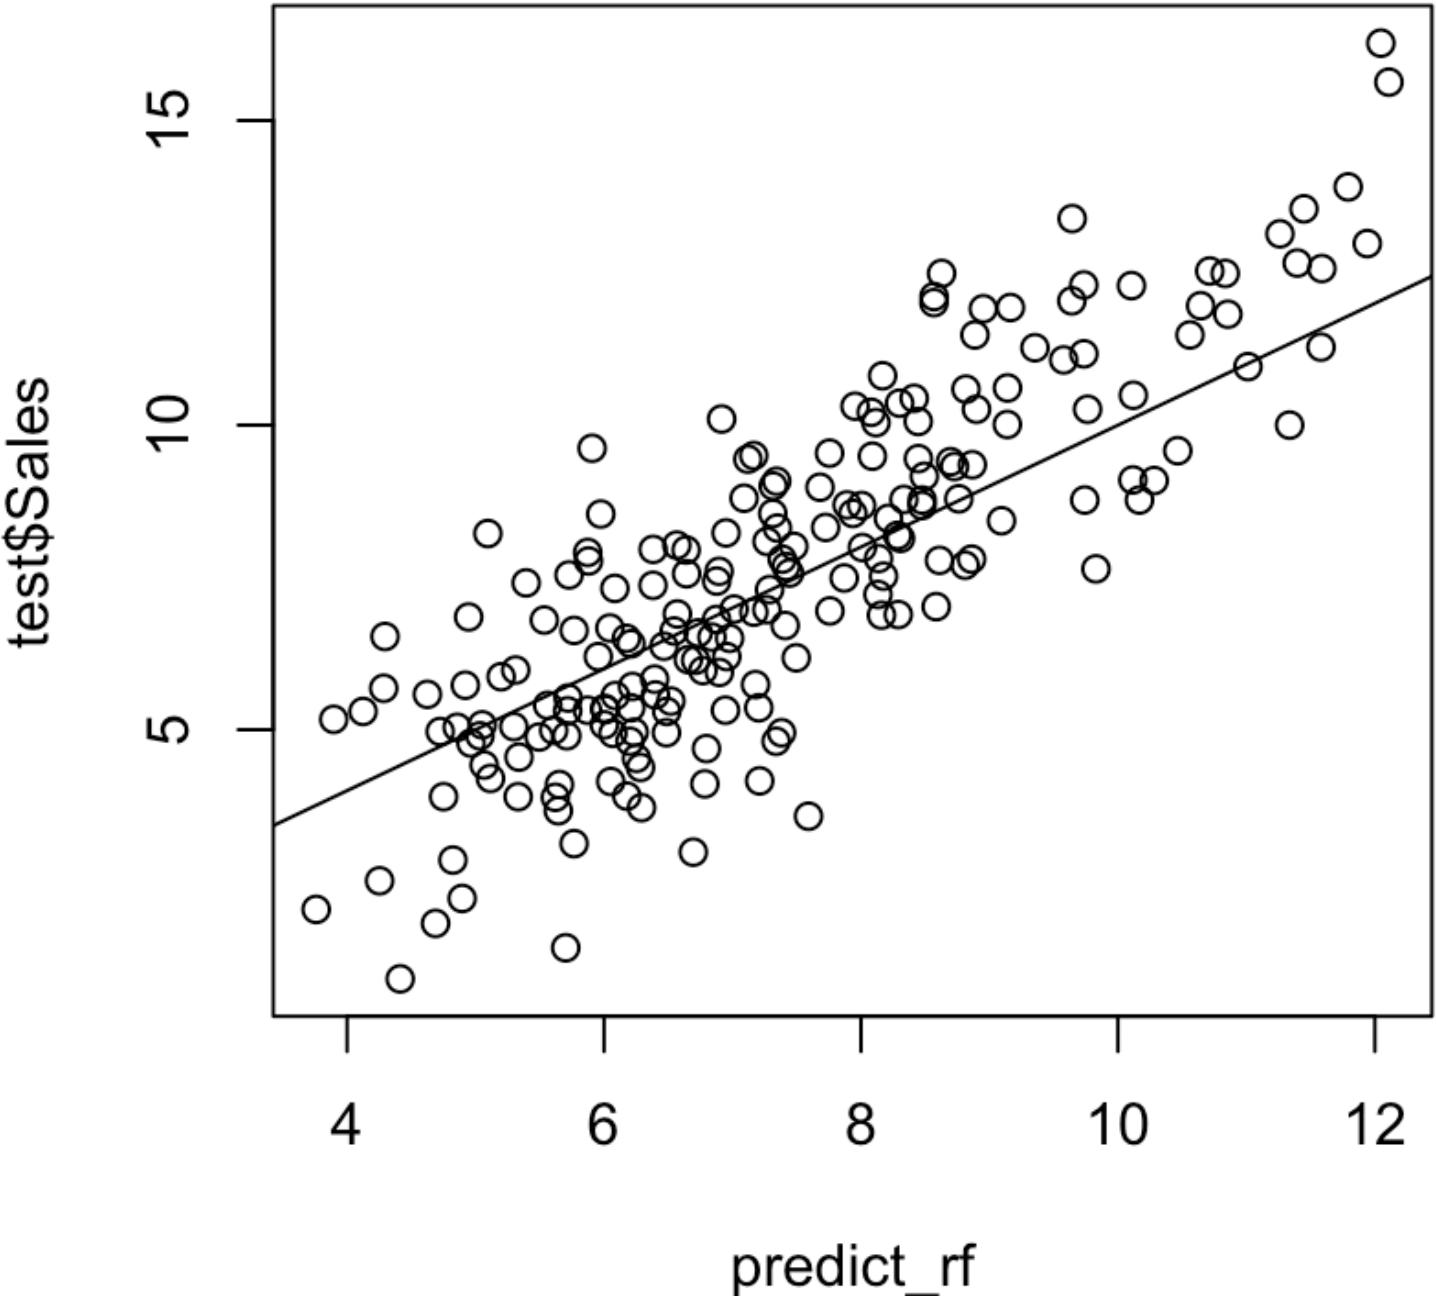

```
> # Random Forest  
> set.seed(124)  
> train = sample(1:nrow(Carseats), 200)  
> test = Carseats[-train,]  
> model_rf = randomForest(Sales ~ ., data = Carseats,subset = train,importance=TRUE)  
> predict_rf = predict(model_rf, test)  
> mean((predict_rf-test$Sales)^2)  
[1] 3.10543
```

Random Forest (with specific features)

- MSE = 2.67

```
> set.seed(124)
> model_rf = randomForest(Sales ~ ., data = Carseats, subset = train, mtry=6, importance=TRUE)
> predict_rf = predict(model_rf, test)
> mean((predict_rf-test$Sales)^2)
[1] 2.672282
> plot(predict_rf, test$Sales)
> abline(0,1)
> summary(model_rf)
```

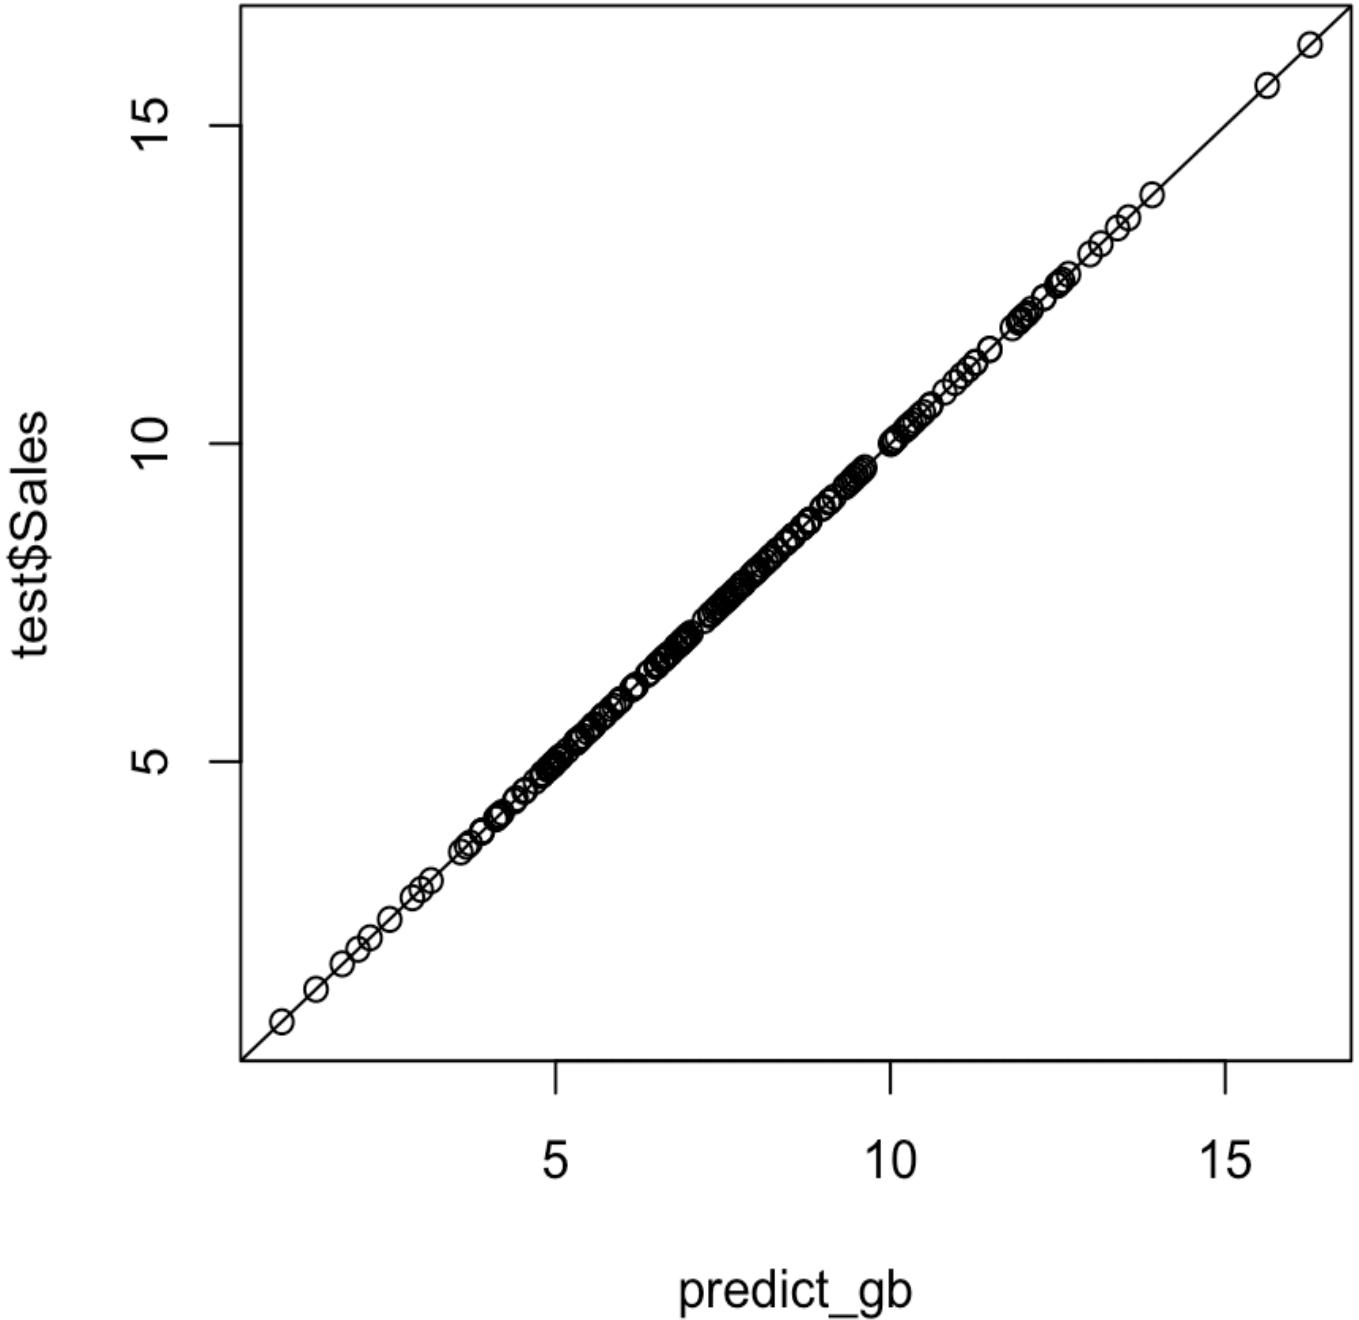

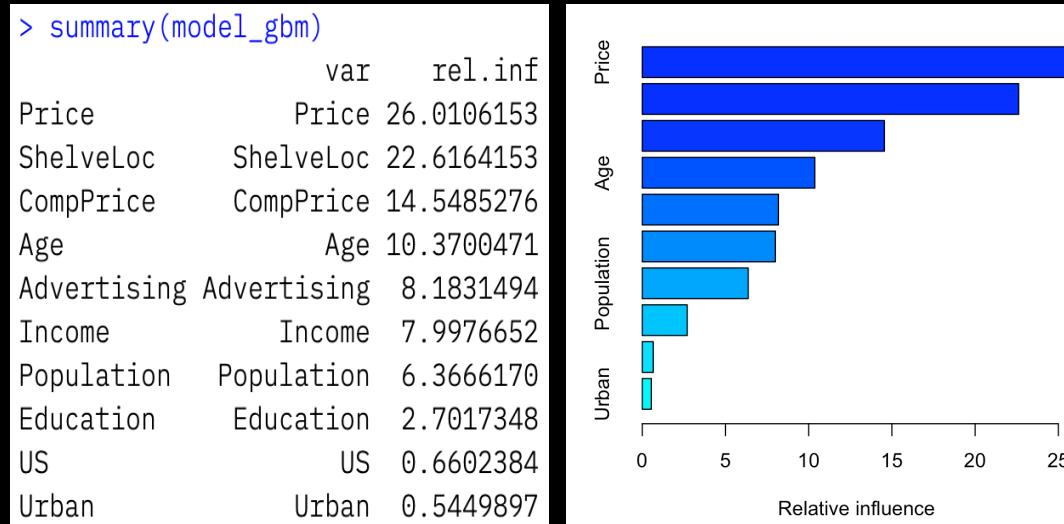

GBM

(Gradient Boosting)

- MSE = 0.00001193749

```
> # GBM
> set.seed(124)
> model_gbm = gbm(Sales ~ ., data = Carseats, distribution = "gaussian",
+                   n.trees = 5000, interaction.depth = 4)
> predict_gb = predict(model_gbm, newdata = test, n.trees = 5000)
> mean((predict_gb - test$Sales)^2)
[1] 1.193749e-05
```

Need for the usage

- Improvise on accuracy, predictive performance
- Ensemble process to increase accuracy and reduce variation
- In case of Bagging: Important feature is around – variable importance
- Can not visualize in bagging scenario (Accuracy goes up, Interpretability down) compared to the way it used to be in simple decision trees
- Ranking of features happen based on different type of techniques:
 - For regression – Residual Sum of squares
 - For classification – Gini coefficient
- Different tactics for bagging and boosting
 - Bagging – parallel execution philosophy
 - Boosting – sequential execution philosophy

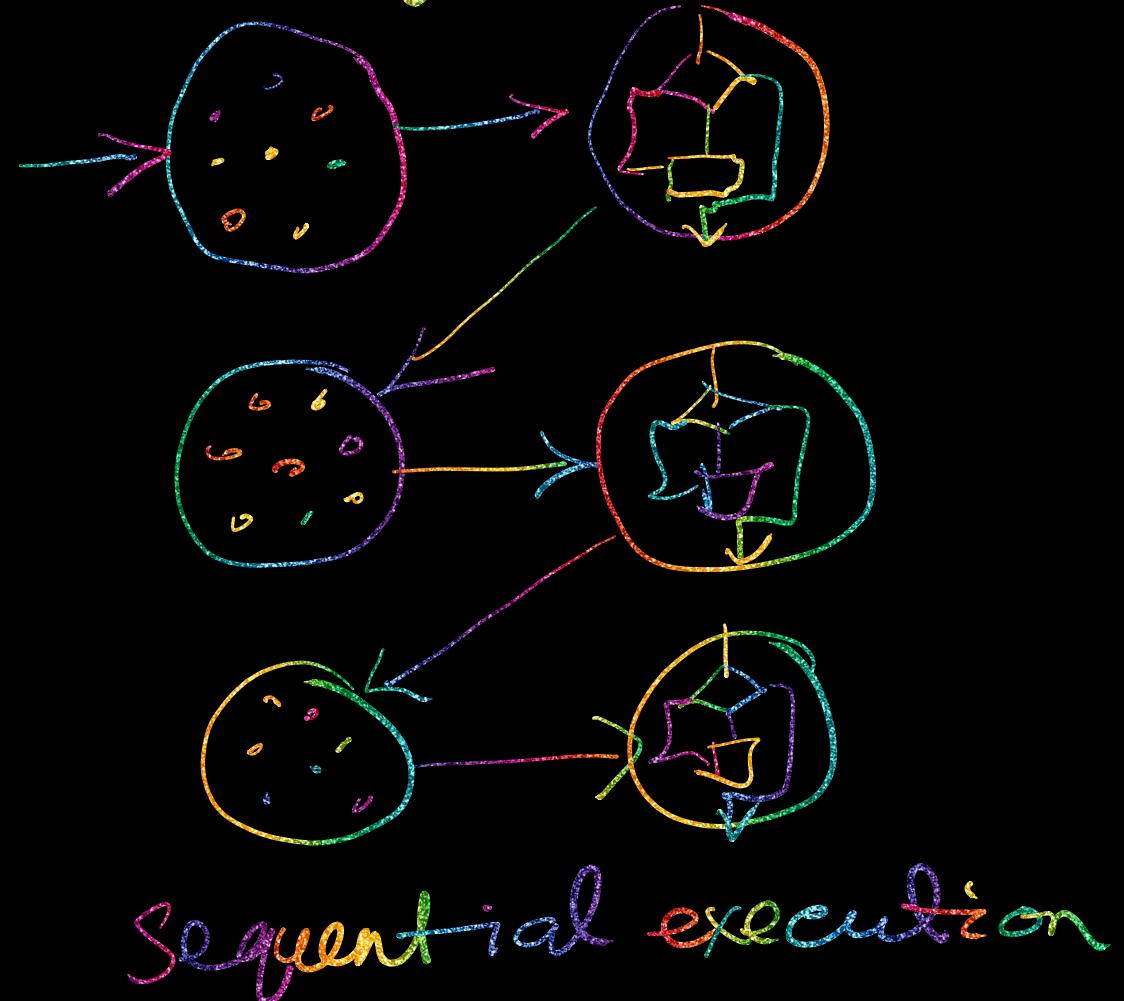

Bagging vs Boosting

Similarities	Dis-similarities
<ul style="list-style-type: none">○ Both are ensemble methods○ Use random sampling to generate several training sets○ Make the final decision by averaging N learners or by majority voting (depending on Regression / Classification type of problems)○ Good at reducing variance○ Provide higher stability and better predicting power for accuracy	<ul style="list-style-type: none">○ Bagging uses parallel execution whereas Boosting performs sequential execution○ Multiple models built independently for Bagging (N models), whereas Boosting experiments including new models that do well where previous models fail○ Boosting determines weighted data approach to tip the scales in favor of difficult cases. i.e. it gives more weightage to those that performs well on training data○ Boosting tries to reduce bias○ Bagging solves the over-fitting issue while Boosting may even increase it.

Bagging and Boosting

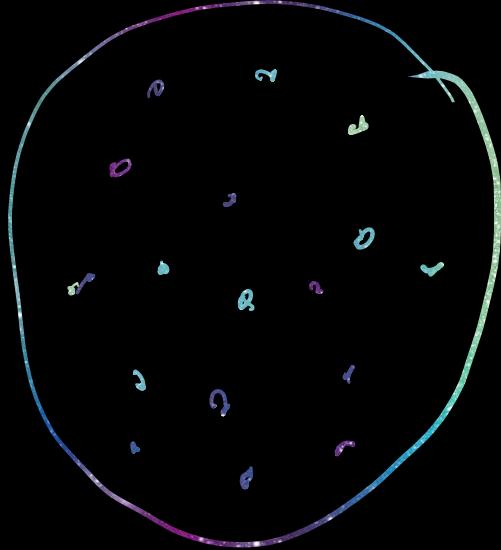

Boosting

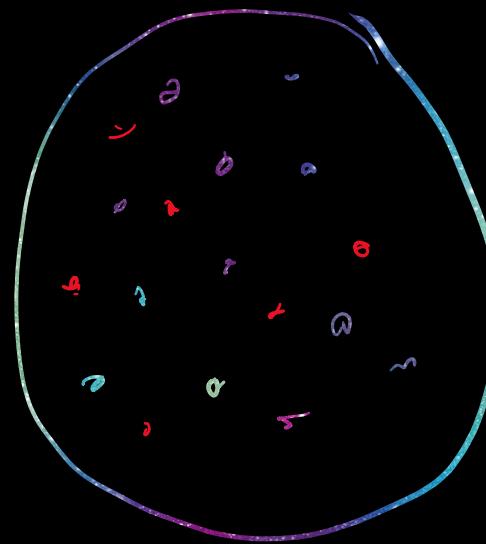

Difference in philosophies illustrated

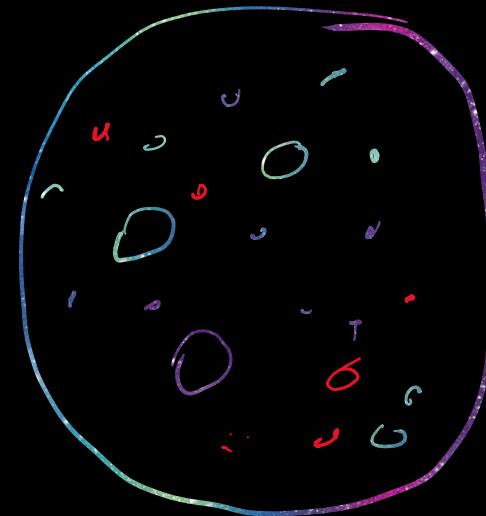

Normal single tree based learning vs Bagging vs Boosting

Complete training set is being used. This is for a single tree based learning approach

Random sampling with replacement is being used. Bootstrapping is used. This is bagging scenario.

Random sampling with replacement over weighted data in a sequential manner. This is boosting scenario.

Algorithms

- Random Forest
- Gradient Boosting (GBM)
- AdaBoost (Adaptive Boosting)
- XGBoost (eXtreme Gradient Boosting)
- catBoost
- LightGBM (Light Gradient Boosting)

Deep dive
on few
algorithms...

Random Forest

Original Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
No	No	No	125	No
Yes	Yes	Yes	180	Yes
Yes	Yes	No	210	No
Yes	No	Yes	167	Yes

Bootstrapped Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	Yes	180	Yes
No	No	No	125	No
Yes	No	Yes	167	Yes
Yes	No	Yes	167	Yes

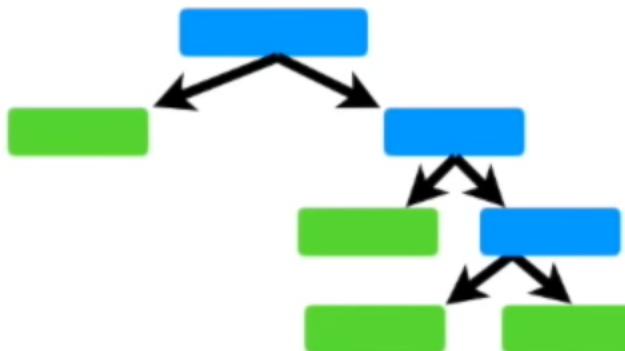

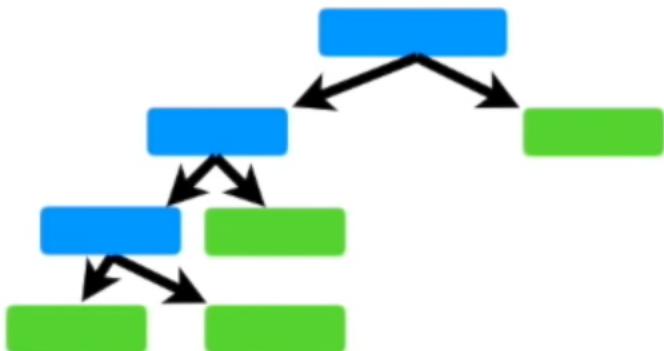

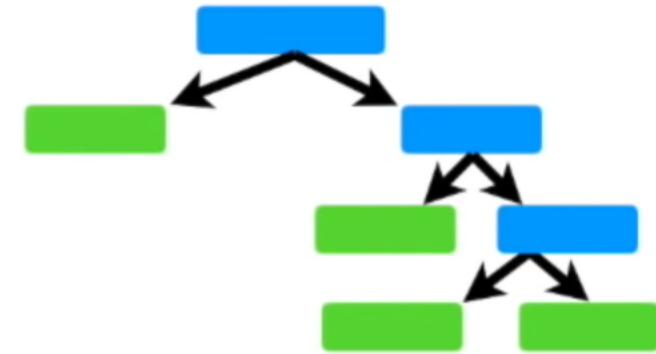

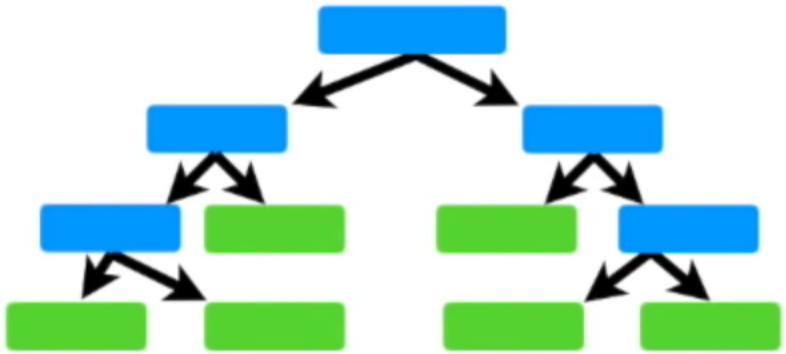

...and here it is.

Step 2: Create a decision tree using the bootstrapped dataset, but only use a random subset of variables (or columns) at each step.

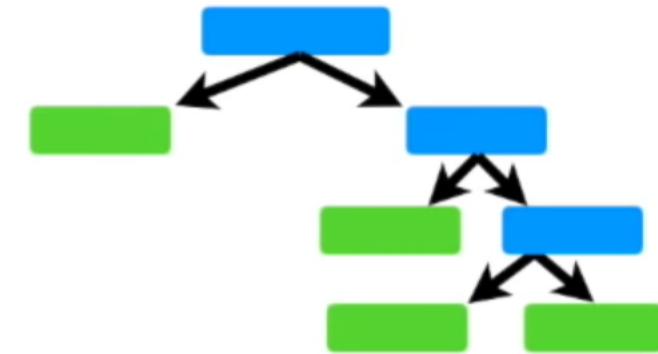

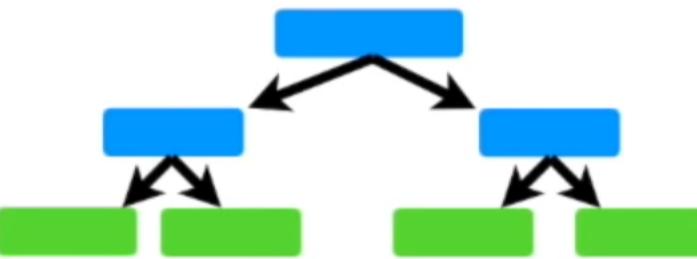

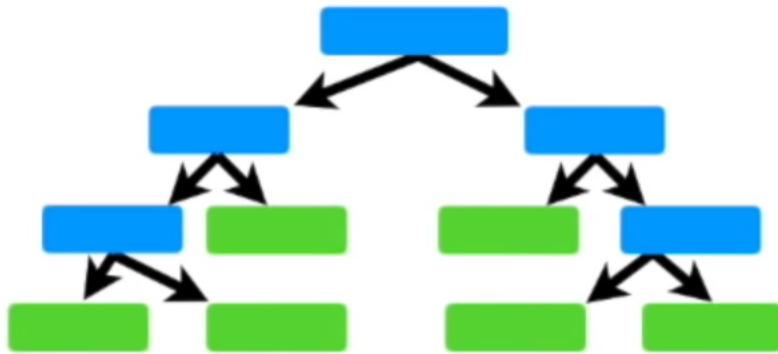

Bootstrapped Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	Yes	180	Yes
No	No	No	125	No
Yes	No	Yes	167	Yes
Yes	No	Yes	167	Yes

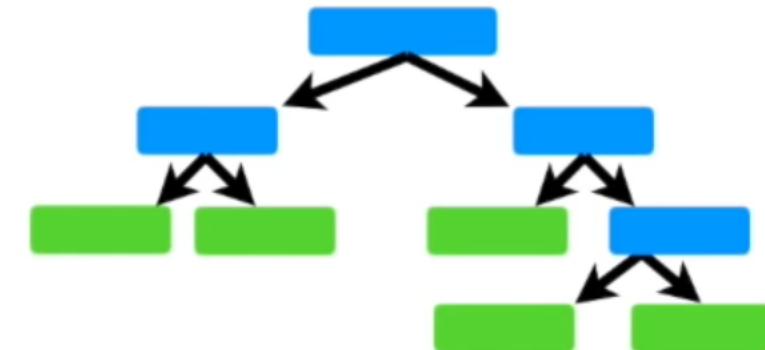

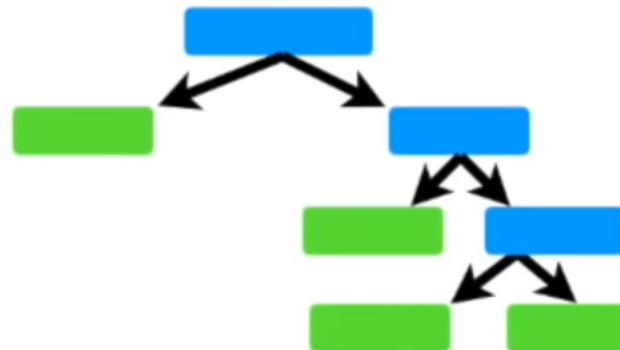

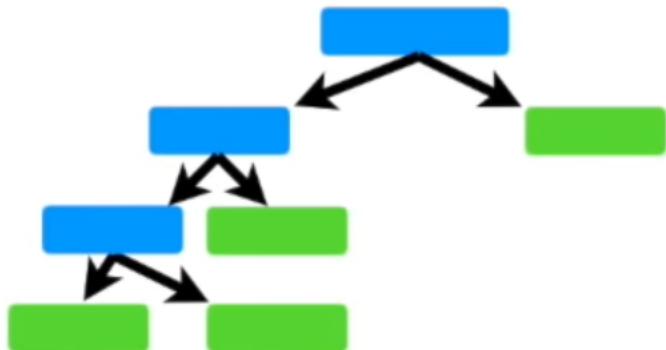

Now go back to Step 1 and repeat: Make a new bootstrapped dataset and build a tree considering a subset of variables at each step.

Using a bootstrapped sample and considering only a subset of the variables at each step results in a wide variety of trees.

The variety is what makes random forests more effective than individual decision trees.

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	No	No	168	

...and now we want to know if they have heart disease or not.

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	No	No	168	

After running the data down all of the trees in the random forest, we see which option received more votes.

Typically, about 1/3 of the original data does not end up in the bootstrapped dataset.

Original Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
No	No	No	125	No
Yes	Yes	Yes	180	Yes
Yes	Yes	No	210	No
Yes	No	Yes	167	Yes

Bootstrapped Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	Yes	180	Yes
No	No	No	125	No
Yes	No	Yes	167	Yes
Yes	No	Yes	167	Yes

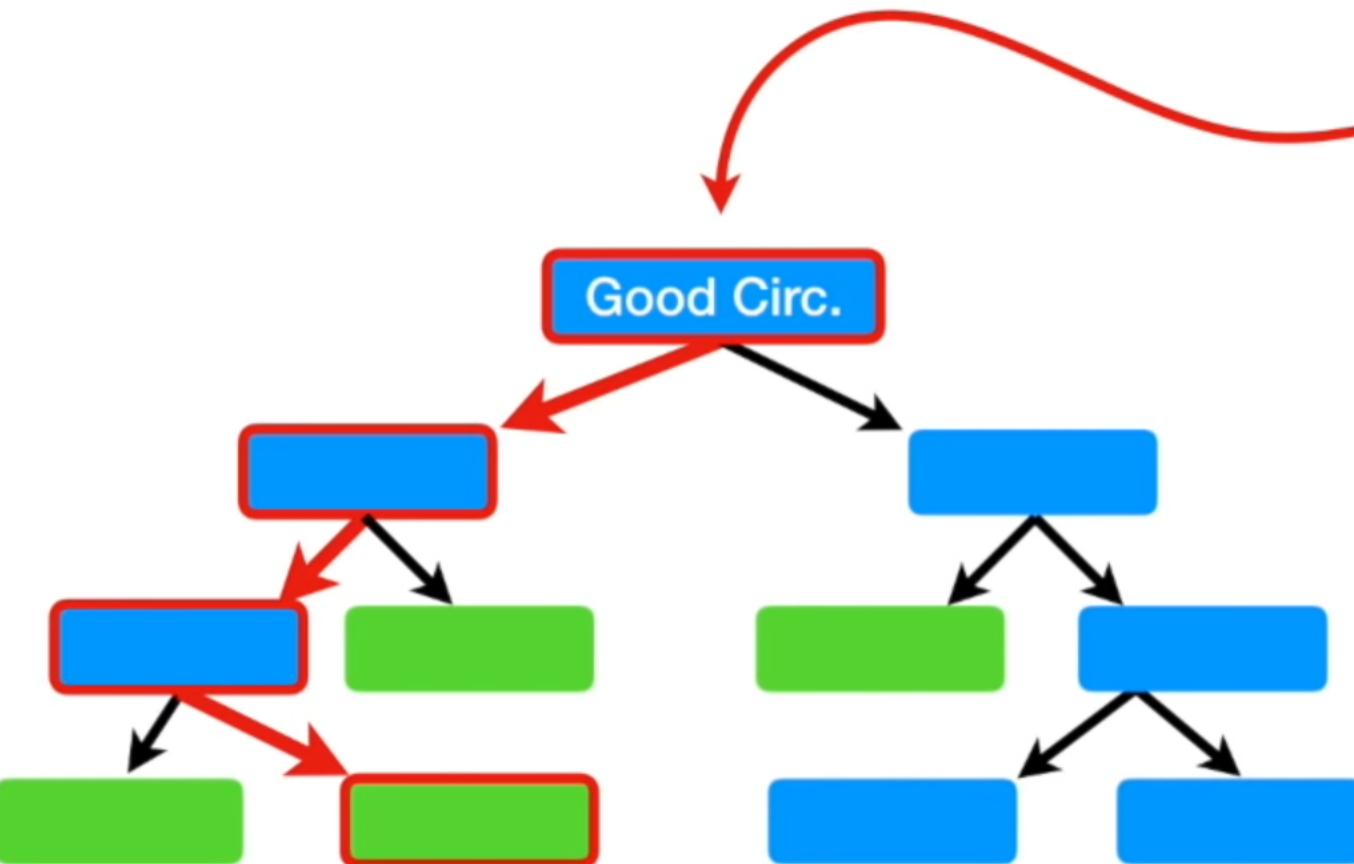

Original Dataset

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
No	No	No	125	No
Yes	Yes	Yes	180	Yes
Yes	Yes	No	210	No
Yes	No	Yes	167	Yes

This is called the
“Out-Of-Bag Dataset”

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	No	210	No

...we can run it through and see if it correctly classifies the sample as
“No Heart Disease”

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	No	210	No

Classification of the Out-Of-Bag sample

Yes

1

No

3

Since the label with the most votes wins, it is the label that we assign this Out-of-Bag sample.

In this case, the Out-of-Bag sample is correctly labeled by the Random Forest.

Chest Pain	Good Blood Circ.	Blocked Arteries	Weight	Heart Disease
Yes	Yes	No	210	No

Classification of the Out-Of-Bag sample

Yes	No
1	3

Classification of the Out-Of-Bag sample

Yes	No
4	0

Classification of the Out-Of-Bag sample

Yes	No
3	1

etc... etc... etc...

Ultimately, we can measure how accurate our random forest is by the proportion of Out-Of-Bag samples that were correctly classified by the Random Forest.

The proportion of Out-Of-Bag samples that were *incorrectly* classified is the “**Out-Of-Bag Error**”

In other words...

...change the number of
variables used per step...

1) Build a Random Forest

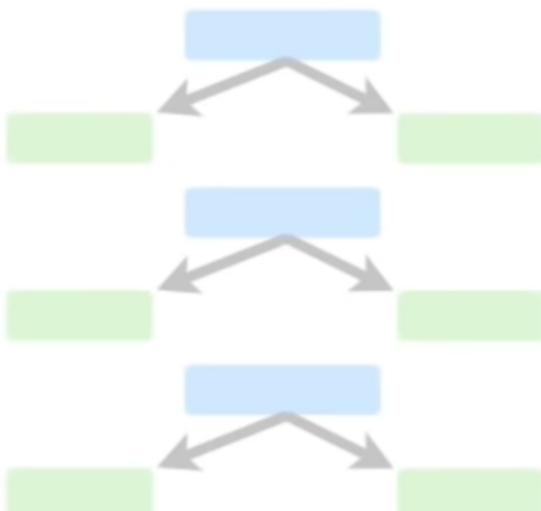

2) Estimate the accuracy of a Random Forest.

Do this for a bunch of
times and then choose the
one that is most accurate.

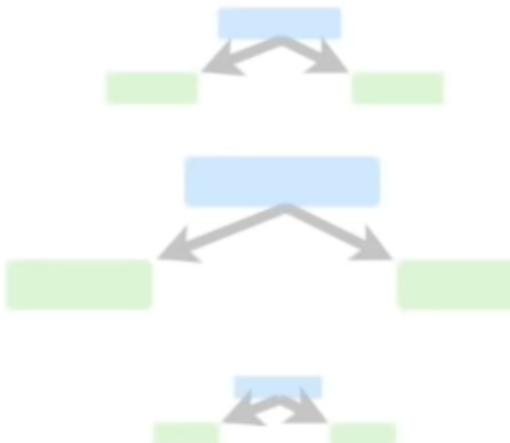

AdaBoost

To review, the three ideas behind **AdaBoost** are...

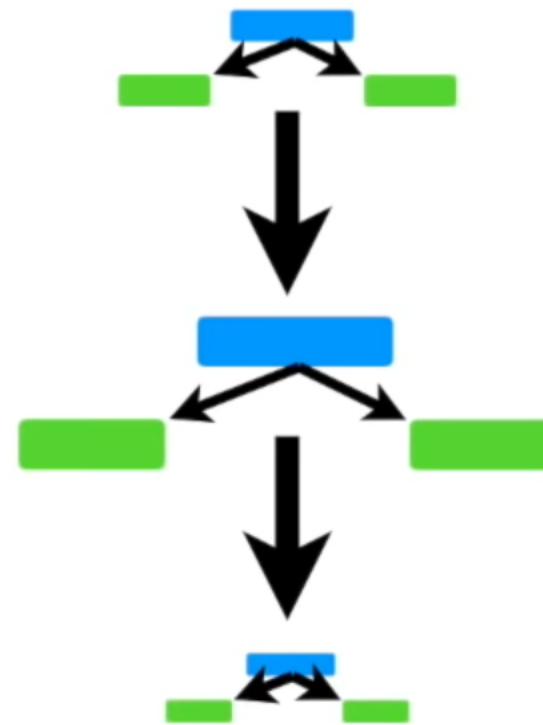

1) AdaBoost combines a lot of “weak learners” to make classifications. The weak learners are almost always **stumps**.

2) Some **stumps** get more say in the classification than others.

3) Each **stump** is made by taking the previous **stump's** mistakes into account.

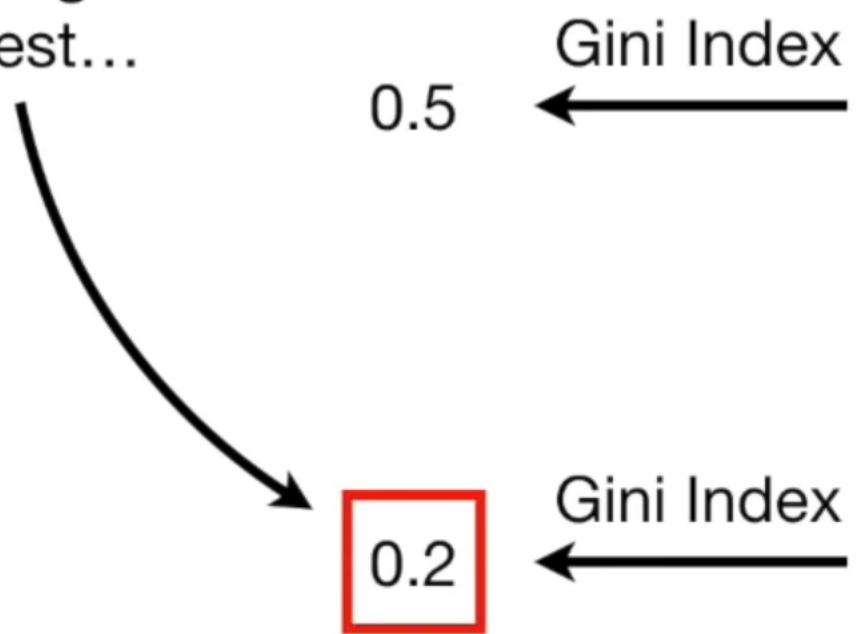

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease
Yes	Yes	205	Yes
No	Yes	180	Yes
Yes	No	210	Yes
Yes	Yes	167	Yes
No	Yes	156	No
No	Yes	125	No
Yes	No	168	No
Yes	Yes	172	No

First, we'll start with some data.

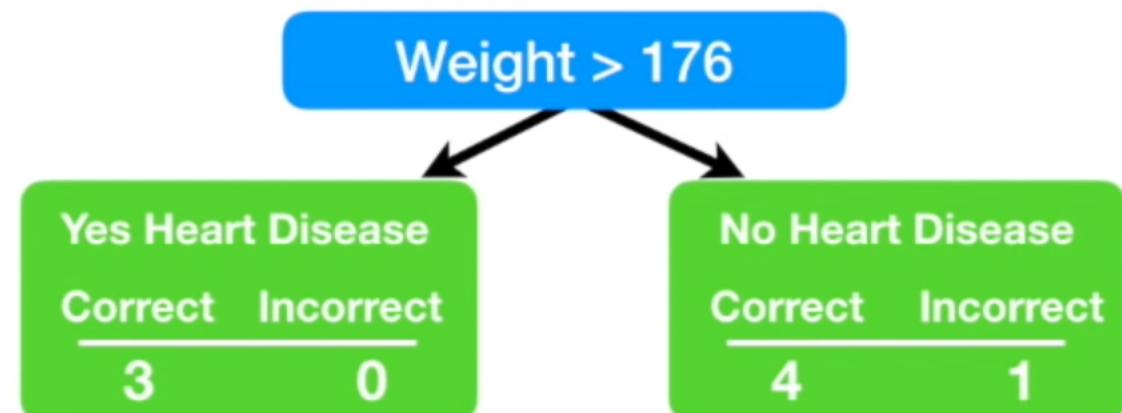

The **Gini Index** for
Patient Weight is
the lowest...

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight
Yes	Yes	205	Yes	1/8
No	Yes	180	Yes	1/8
Yes	No	210	Yes	1/8
Yes	Yes	167	Yes	1/8
No	Yes	156	No	1/8
No	Yes	125	No	1/8
Yes	No	168	No	1/8
Yes	Yes	172	No	1/8

The **Total Error** for a stump is the sum of the weights associated with the *incorrectly* classified samples.

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight
Yes	Yes	205	Yes	1/8
No	Yes	180	Yes	1/8
Yes	No	210	Yes	1/8
Yes	Yes	167	Yes	1/8
No	Yes	156	No	1/8
No	Yes	125	No	1/8
Yes	No	168	No	1/8
Yes	Yes	172	No	1/8

We use the **Total Error** to determine **Amount of Say** this stump has in the final classification with the following formula:

$$\text{Amount of Say} = \frac{1}{2} \log\left(\frac{1 - \text{Total Error}}{\text{Total Error}}\right)$$

Now we need to learn how to modify the weights so that the next stump will take the errors that the current stump made into account.

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight
Yes	Yes	205	Yes	1/8
No	Yes	180	Yes	1/8
Yes	No	210	Yes	1/8
Yes	Yes	167	Yes	1/8
No	Yes	156	No	1/8
No	Yes	125	No	1/8
Yes	No	168	No	1/8
Yes	Yes	172	No	1/8

New Sample Weight = sample weight $\times e^{\text{amount of say}}$

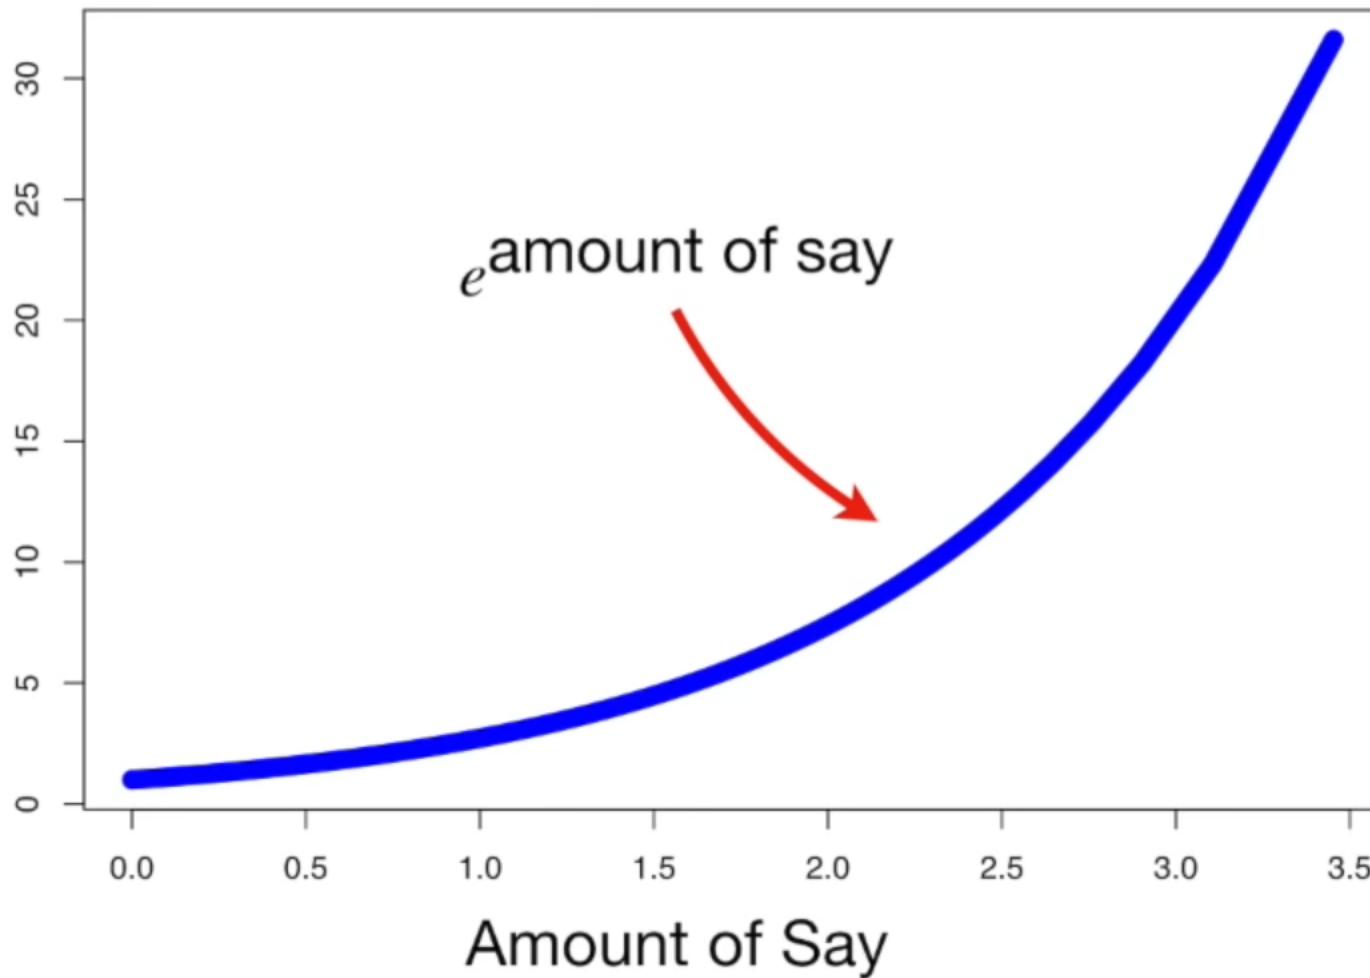

This is the formula we will use to *increase* the **Sample Weight** for the sample that was *incorrectly classified*.

New Sample Weight = sample weight $\times e^{\text{amount of say}}$

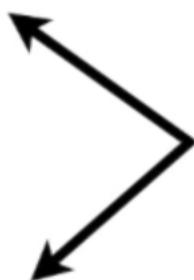

$$= \frac{1}{8} e^{\text{amount of say}}$$

$$= \frac{1}{8} e^{0.97} = \frac{1}{8} \times 2.64 = 0.33$$

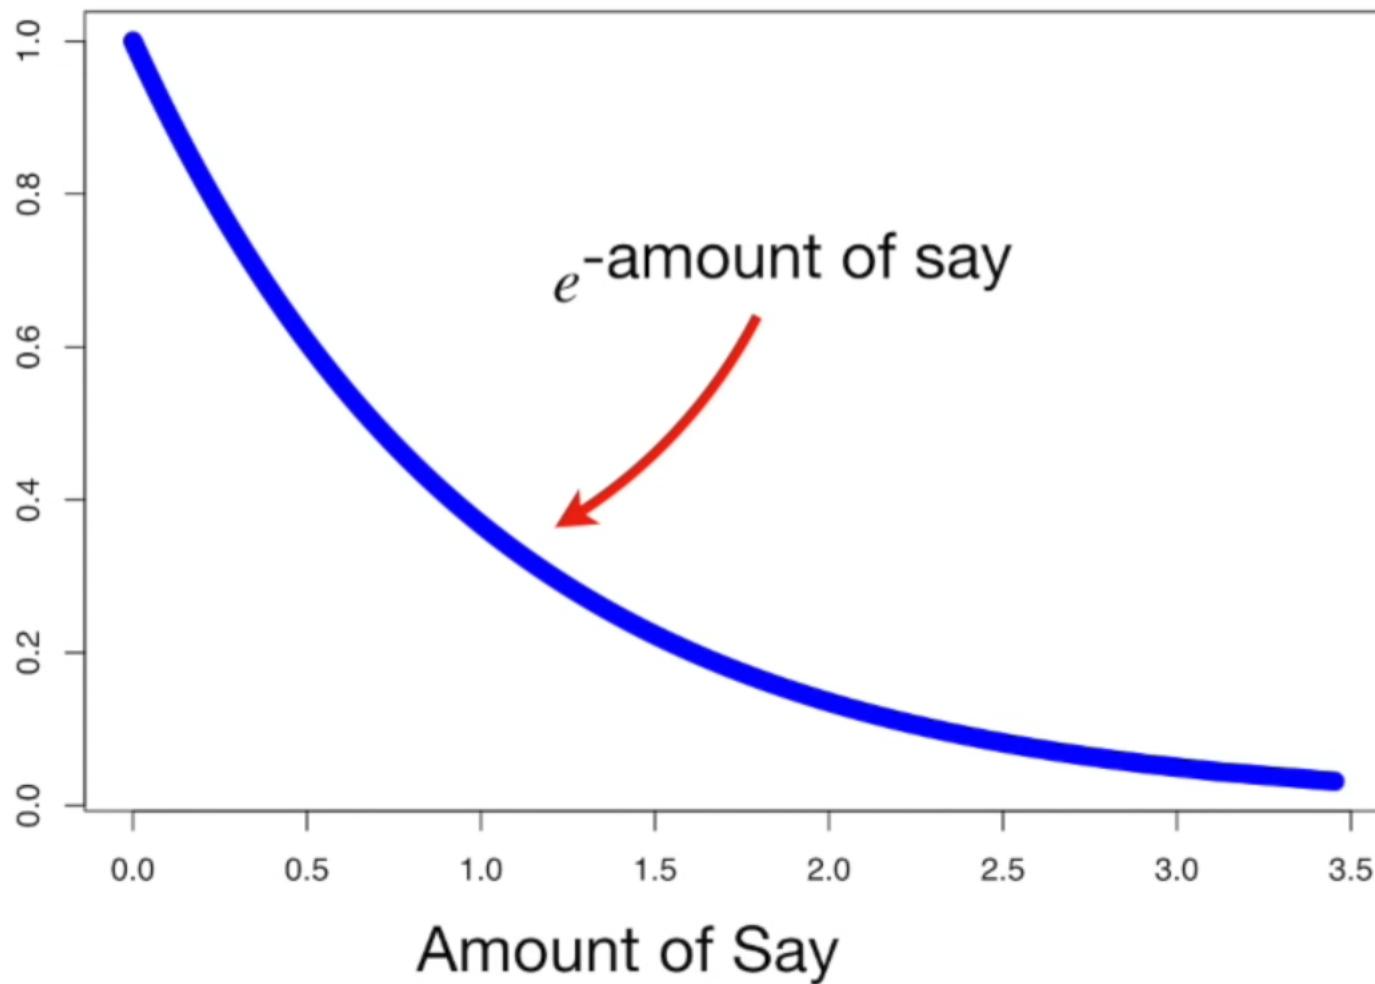

That means the new **Sample Weight** is **0.33**, which is *more* than the old one ($1/8 = 0.125$).

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight
Yes	Yes	205	Yes	1/8
No	Yes	180	Yes	1/8
Yes	No	210	Yes	1/8
Yes	Yes	167	Yes	1/8
No	Yes	156	No	1/8
No	Yes	125	No	1/8
Yes	No	168	No	1/8
Yes	Yes	172	No	1/8

Now we need to decrease the **Sample Weights** for all of the *correctly* classified samples.

New Sample Weight = sample weight $\times e^{-\text{amount of say}}$

$$= \frac{1}{8} e^{-\text{amount of say}}$$

$$= \frac{1}{8} e^{-0.97} = \frac{1}{8} \times 0.38 = 0.05$$

The new **Sample Weight** is **0.05**, which is less than the old one ($1/8 = 0.125$).
↑

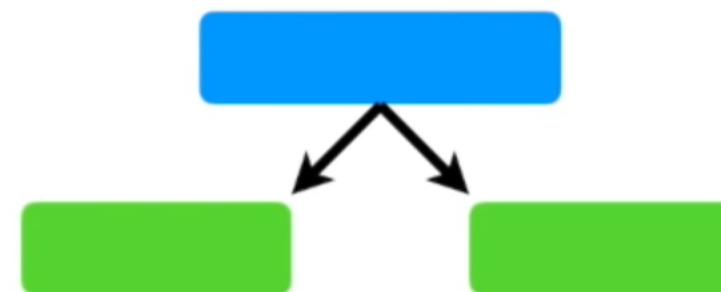

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight	New Weight	Norm. Weight
Yes	Yes	205	Yes	1/8	0.05	0.07
No	Yes	180	Yes	1/8	0.05	0.07
Yes	No	210	Yes	1/8	0.05	0.07
Yes	Yes	167	Yes	1/8	0.33	0.49
No	Yes	156	No	1/8	0.05	0.07
No	Yes	125	No	1/8	0.05	0.07
Yes	No	168	No	1/8	0.05	0.07
Yes	Yes	172	No	1/8	0.05	0.07

Now, when we add up the **New Sample Weights**, we get **1** (plus or minus a little rounding error).

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease	Sample Weight
Yes	Yes	205	Yes	0.07
No	Yes	180	Yes	0.07
Yes	No	210	Yes	0.07
Yes	Yes	167	Yes	0.49
No	Yes	156	No	0.07
No	Yes	125	No	0.07
Yes	No	168	No	0.07
Yes	Yes	172	No	0.07

Now we can use the modified **Sample Weights** to make the second **stump** in the forest.

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease
No	Yes	156	No
Yes	Yes	167	Yes
No	Yes	125	No
Yes	Yes	167	Yes
Yes	Yes	167	Yes
Yes	Yes	172	No
Yes	Yes	205	Yes
Yes	Yes	167	Yes

...and use the new collection of samples.

Chest Pain	Blocked Arteries	Patient Weight	Heart Disease
No	Yes	156	No
Yes	Yes	167	Yes
No	Yes	125	No
Yes	Yes	167	Yes
Yes	Yes	167	Yes
Yes	Yes	172	No
Yes	Yes	205	Yes
Yes	Yes	167	Yes

Ultimately, the patient is classified as **Has Heart Disease** because this is the larger sum.

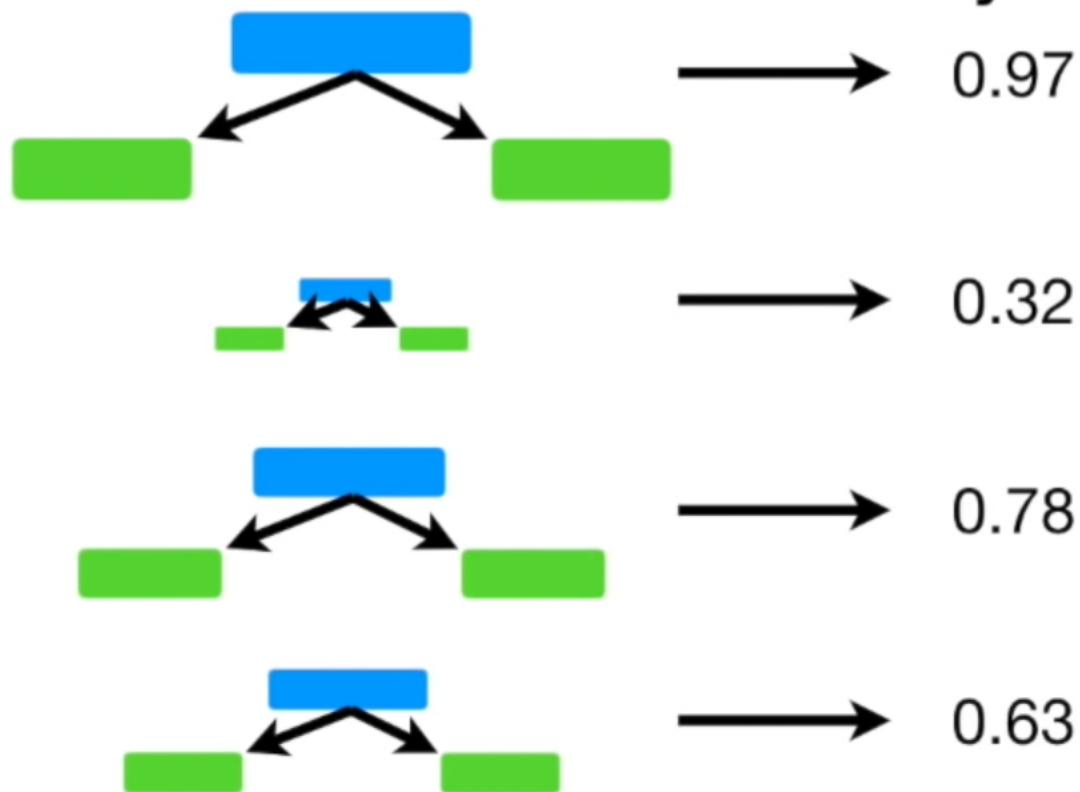

Has Heart Disease

Total = 2.7

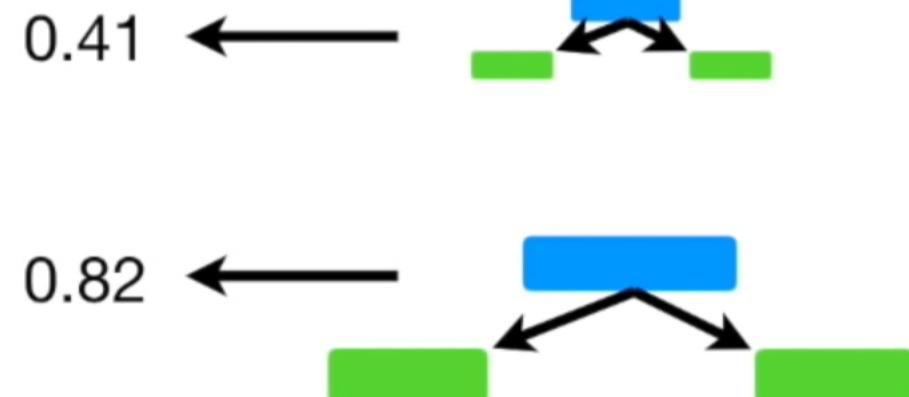

Total = 1.23

Does Not Have Heart Disease

Amount of Say

Amount of Say

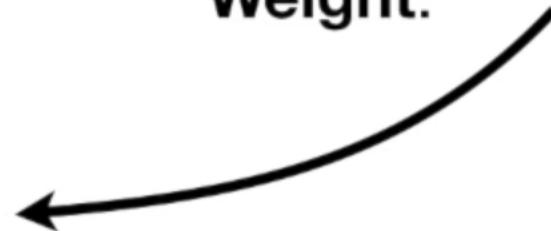

Gradient Boost

AdaBoost and Gradient Boost

- AdaBoost starts by building a very short tree called a Stump. Gradient Boost starts by making a single leaf instead of tree or Stump. The leaf represent an initial guess (average) of all the samples
- AdaBoost and Gradient Boost trees are based on error made by the previous tree but tree build by Gradient Boost is larger than a Stump
- Like AdaBoost, Gradient Boost scales the trees. But Gradient Boost scales all the trees by the same amount

...let's see how the most common
Gradient Boost configuration would
use this **Training Data** to Predict
Weight.

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88
1.6	Green	Female	76
1.5	Blue	Female	56
1.8	Red	Male	73
1.5	Green	Male	77
1.4	Blue	Female	57

Average Weight

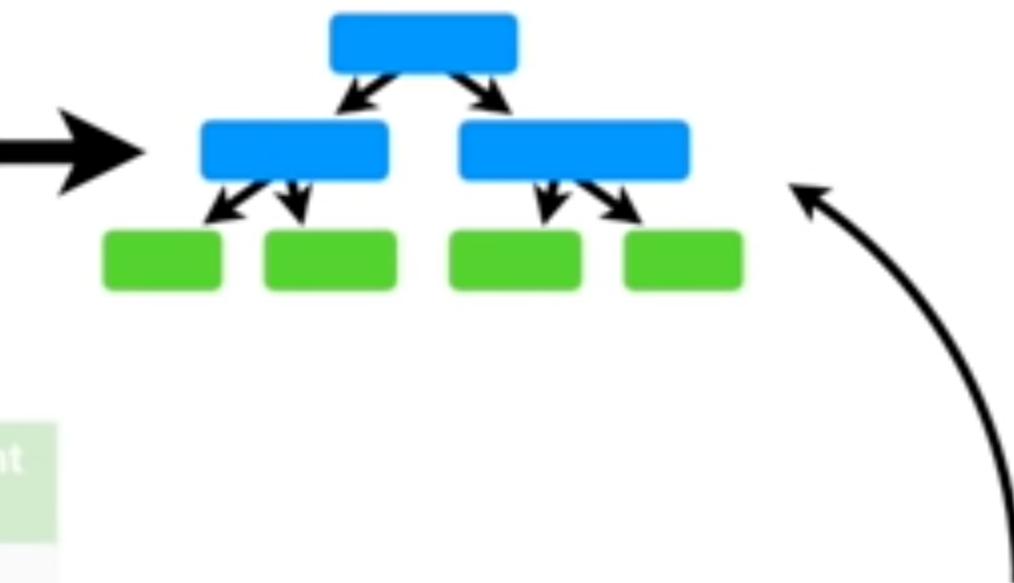

71.2

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88
1.6	Green	Female	76
1.5	Blue	Female	56
1.8	Red	Male	73
1.5	Green	Male	77
1.4	Blue	Female	57

The first thing we do is calculate the average **Weight.**

Average Weight

71.2

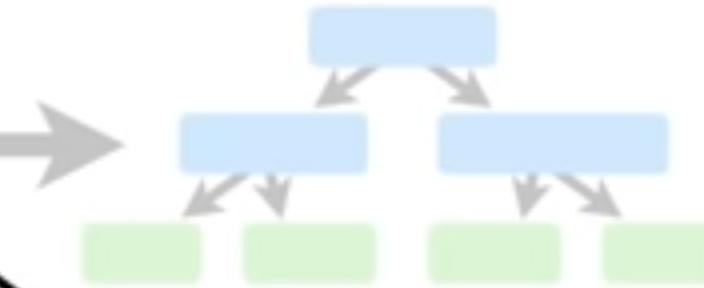

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88
1.6	Green	Female	76
1.5	Blue	Female	56
1.8	Red	Male	73
1.5	Green	Male	77
1.4	Blue	Female	57

The next thing we do is build a tree based on the errors from the first tree.

Average Weight

71.2

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88
1.6	Green	Female	76
1.5	Blue	Female	56
1.8	Red	Male	73
1.5	Green	Male	77
1.4	Blue	Female	57

The errors that the previous tree made are the differences between the **Observed Weights** and the **Predicted Weight, 71.2.**

(Observed Weight - Predicted Weight)

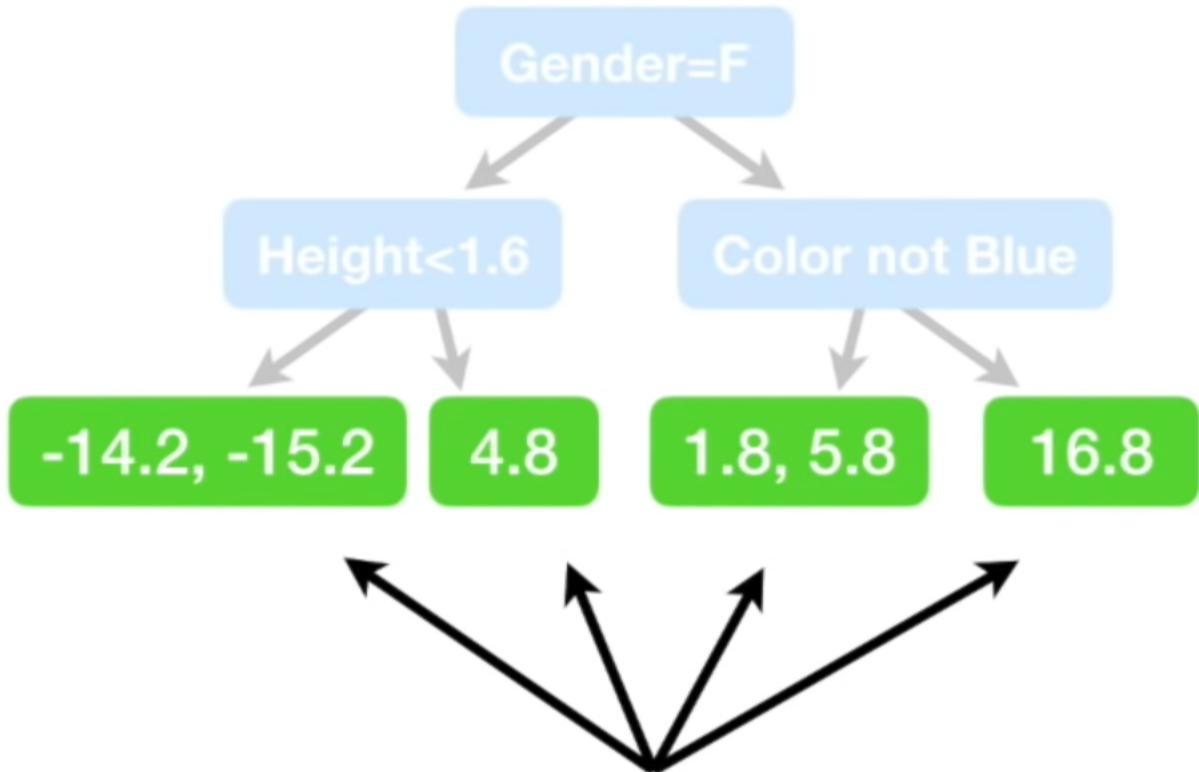

Now we will build a **Tree**, using
Height, Favorite Color and **Gender**...

Height (m)	Favorite Color	Gender	Weight (kg)	Residual
1.6	Blue	Male	88	16.8
1.6	Green	Female	76	4.8
1.5	Blue	Female	56	-15.2
1.8	Red	Male	73	1.8
1.5	Green	Male	77	5.8
1.4	Blue	Female	57	-14.2

...to Predict the Residuals.

Height (m)	Favorite Color	Gender	Weight (kg)	Residual
1.6	Blue	Male	88	16.8
1.6	Green	Female	76	4.8
1.5	Blue	Female	58	-15.2
1.8	Red	Male	73	1.8
1.5	Green	Male	77	5.8
1.4	Blue	Female	57	-14.2

Remember, in this example we are only allowing up to four leaves...

...but when using a larger dataset, it is common to allow anywhere from **8** to **32**.

Average Weight

71.2

Gender=F

Height<1.6

-14.7

Color not Blue

4.8

3.8

16.8

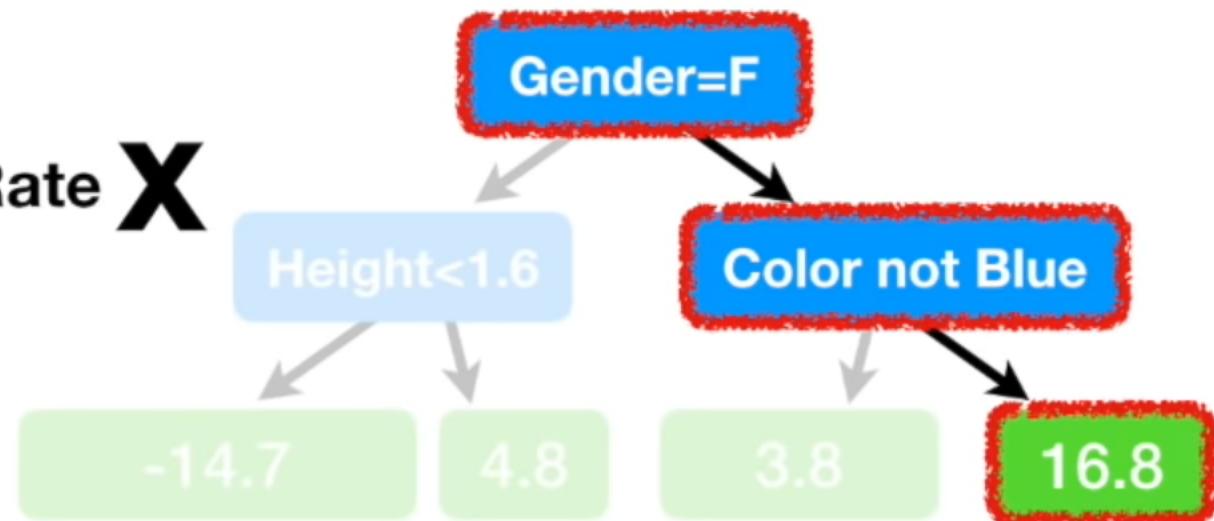

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88

...to make a new
Prediction of an
individual's **Weight** from
the **Training Data**.

Average Weight

71.2

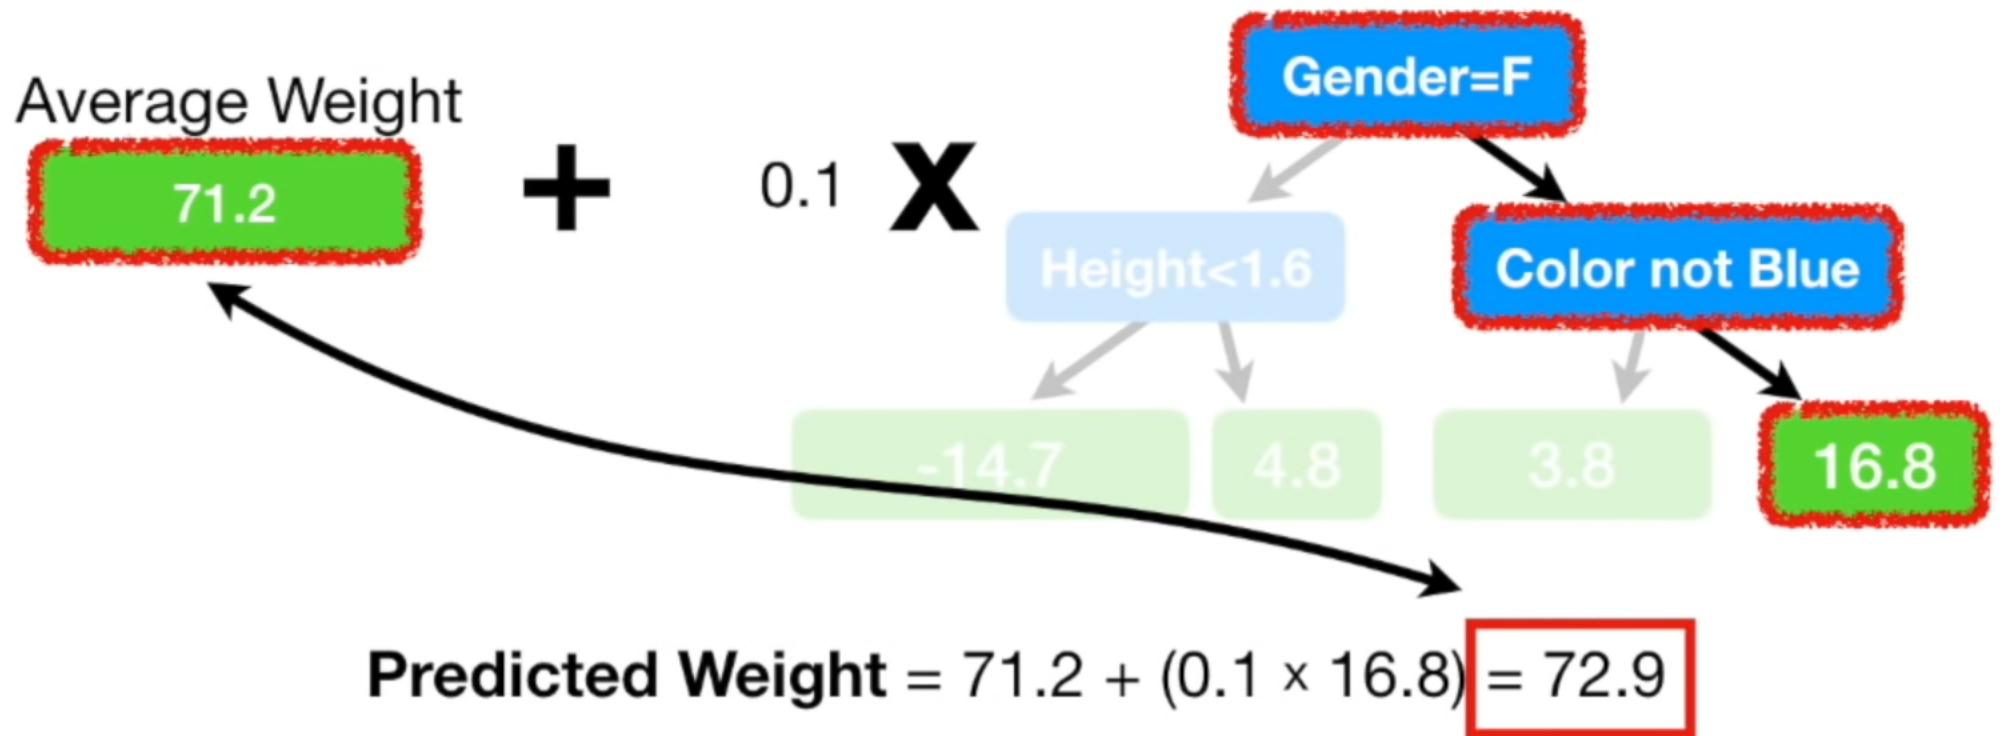

+ Learning Rate \times

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88

Gradient Boost deals with this problem by using a **Learning Rate** to scale the contribution from the new tree.

The **Learning Rate** is a value between **0** and **1**.

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88

...but it's a little bit better than the **Prediction** made with just the original leaf, which predicted that all samples would weigh **71.2**.

Average Weight

71.2

+

0.1

X

Gender=F

Height<1.6

Color not Blue

Residual
16.8
4.8
-15.2
1.8
5.8
-14.2

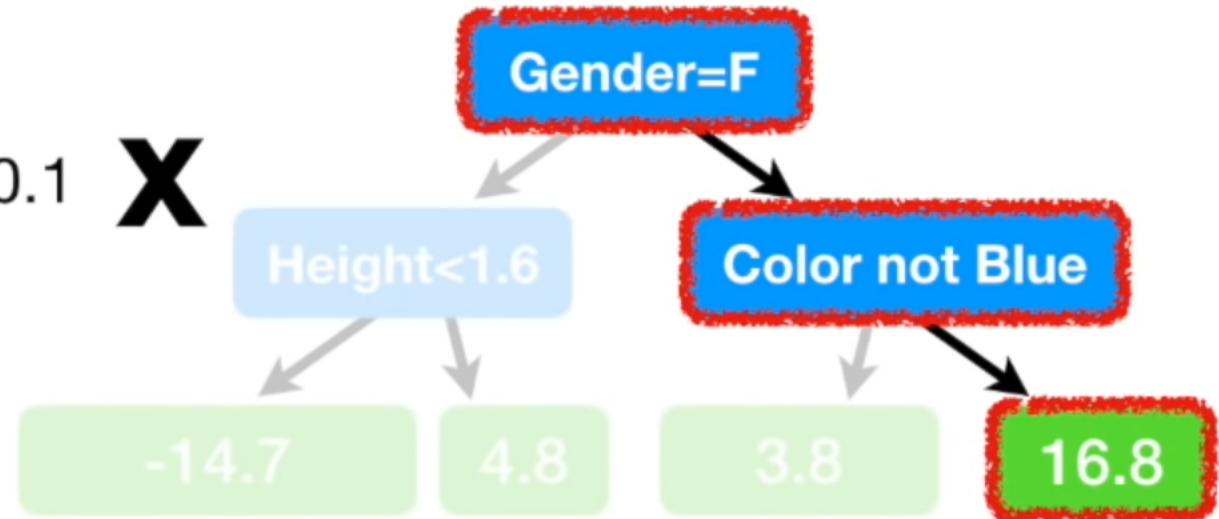

Residual
15.1
4.3
-13.7
1.4
5.4
-12.7

The new **Residuals** are all smaller than before, so we've taken a small step in the right direction.

Average Weight

71.2

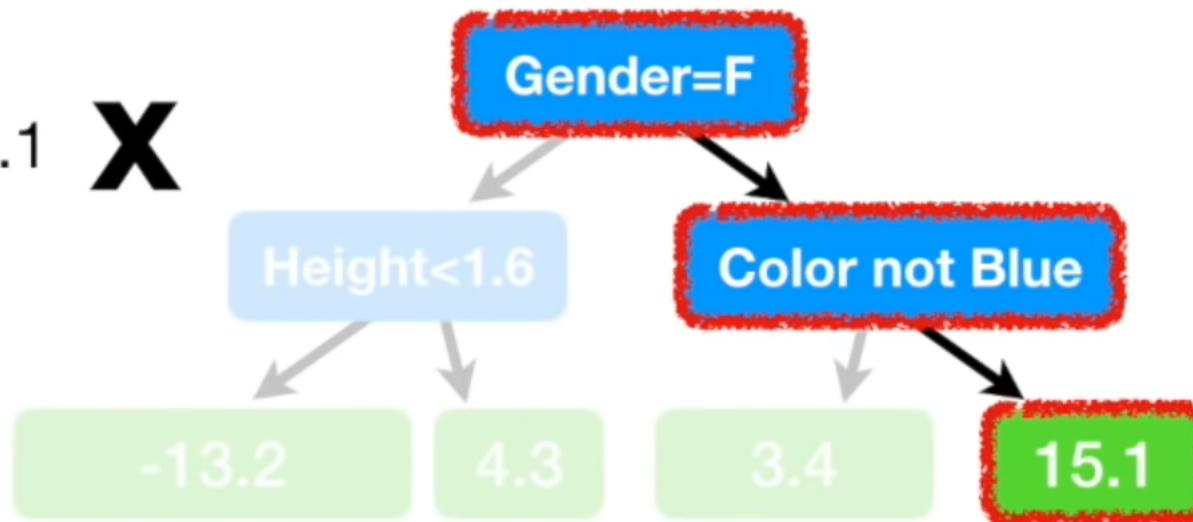

+ 0.1 X

...and the scaled amount
from the second Tree.

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88

+ 0.1 X

Average Weight

71.2

+ 0.1 X

Gender=F

Height<1.6

-14.7

4.8

3.8

16.8

Which is another small step closer to the **Observed Weight**.

$$71.2 + (0.1 \times 16.8) + (0.1 \times 15.1)$$

= 74.4

Height (m)	Favorite Color	Gender	Weight (kg)
1.6	Blue	Male	88

+ 0.1 X

Gender=F

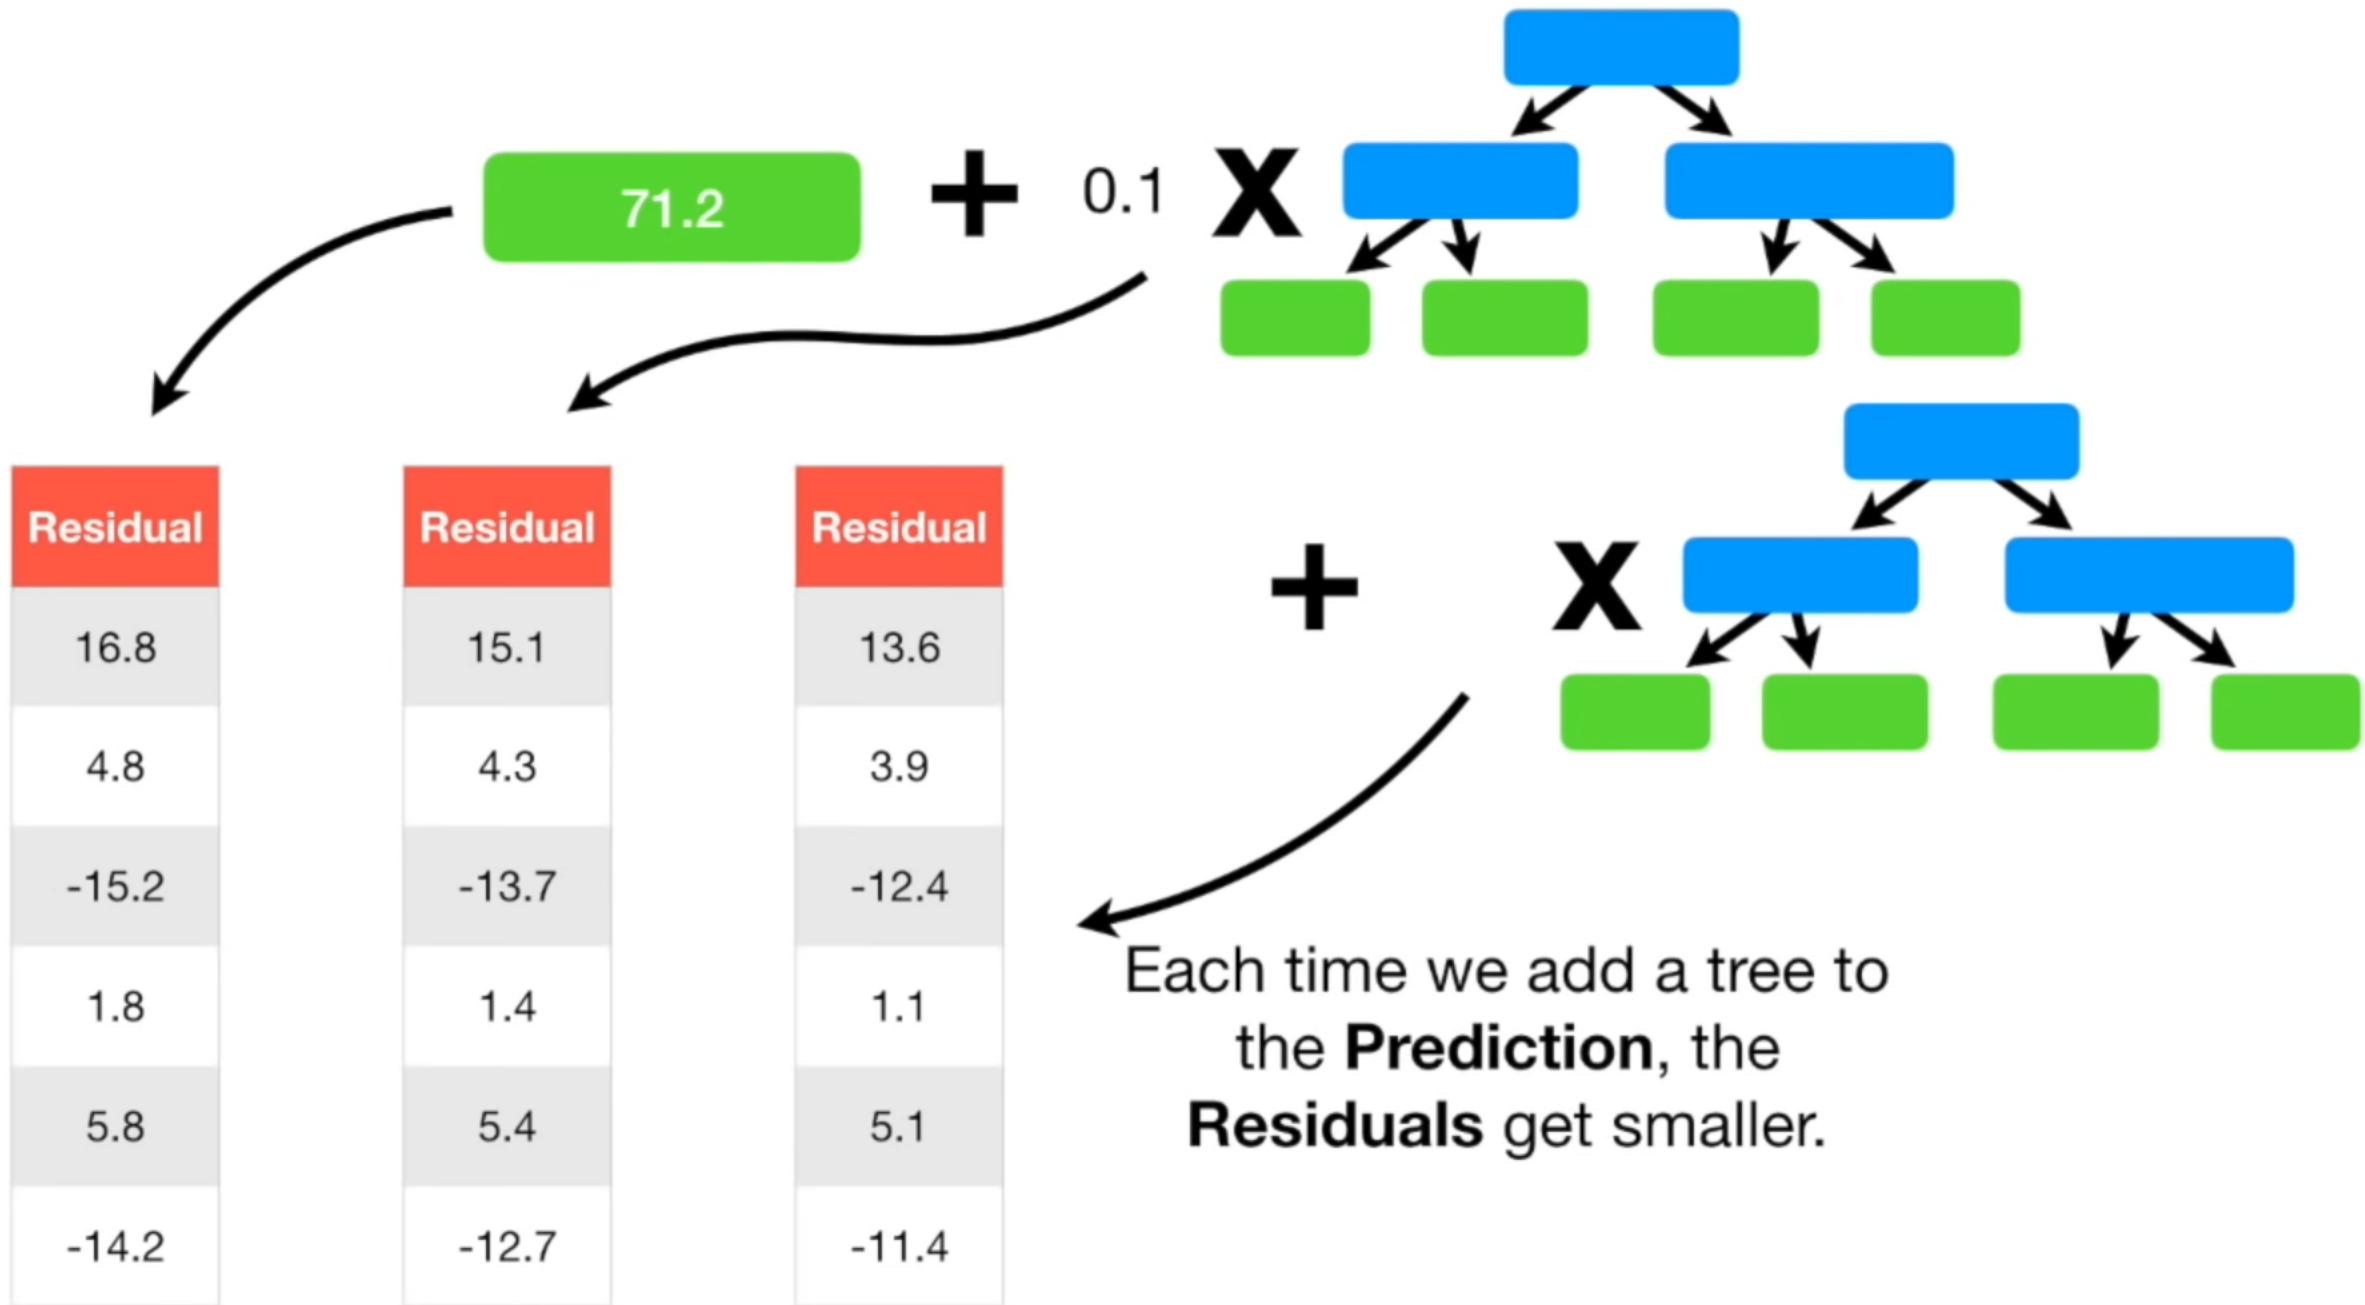

Height<1.6

-13.2

4.3

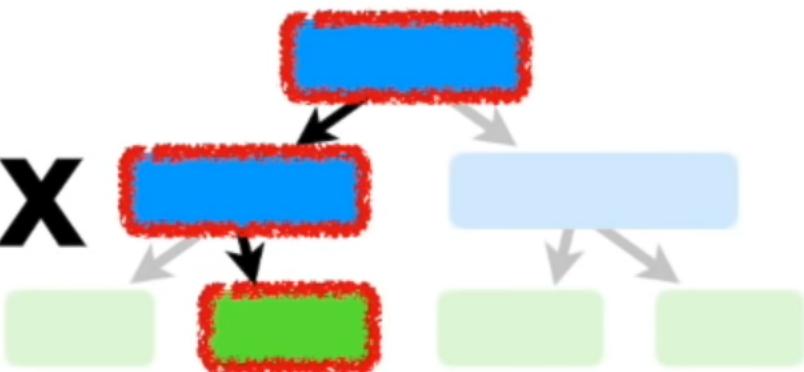

3.4

15.1

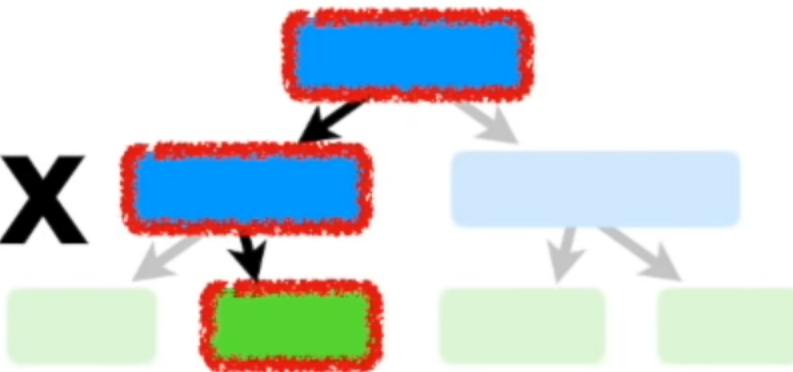

71.2

+ 0.1 X

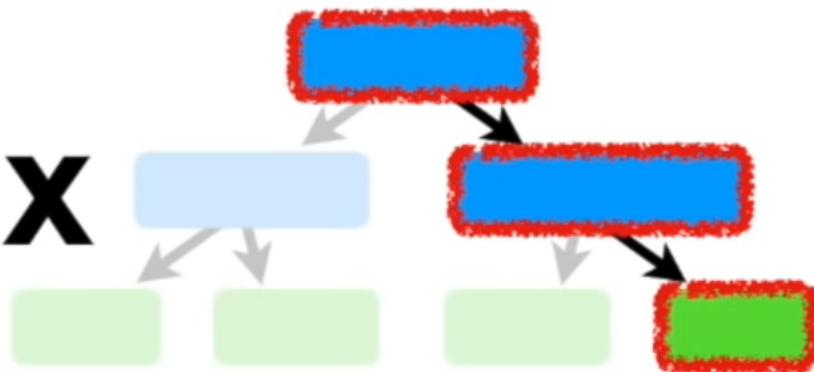

...etc...etc...etc...

+ 0.1 X

Height (m)	Favorite Color	Gender	Weight (kg)
1.7	Green	Female	???

+ 0.1 X

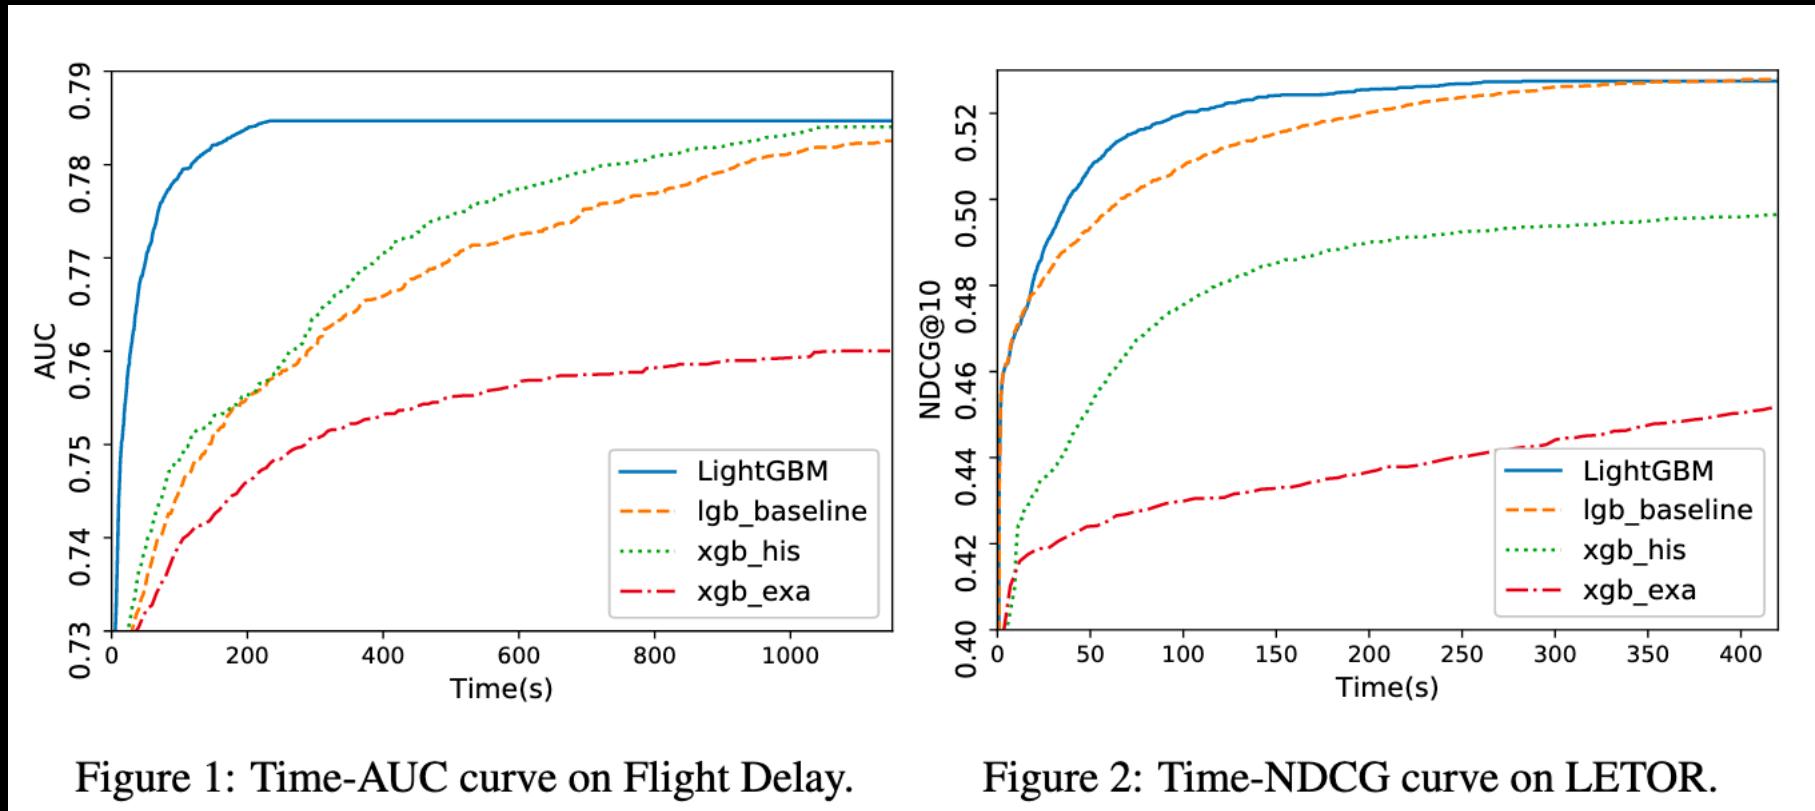

...etc...etc...etc...

Different practice usage in R

- Individual packages / libraries such as randomforest, gbm etc
- Caret package reference
- H2O package reference
